## Abstract

We analyze the computational complexity of type inference for untyped  $\lambda$ -terms in the second-order polymorphic typed  $\lambda$ -calculus ( $F_2$ ) invented by Girard and Reynolds, as well as higher-order extensions  $F_3, F_4, \dots, F_\omega$  proposed by Girard. We prove that recognizing the  $F_2$ -typable terms requires exponential time, and for  $F_\omega$  the problem is nonelementary. We show as well a sequence of lower bounds on recognizing the  $F_k$ -typable terms, where the bound for  $F_{k+1}$  is exponentially larger than that for  $F_k$ .

The lower bounds are based on generic simulation of Turing Machines, where computation is simulated at the expression and type level simultaneously. Non-accepting computations are mapped to non-normalizing reduction sequences, and hence non-typable terms. The accepting computations are mapped to typable terms, where higher-order types encode reduction sequences, and first-order types encode the entire computation as a circuit, based on a unification simulation of Boolean logic. A primary technical tool in this reduction is the composition of polymorphic functions having different domains and ranges.

These results are the first nontrivial lower bounds on type inference for the Girard/Reynolds system as well as its higher-order extensions. We hope that the analysis provides important combinatorial insights which will prove useful in the ultimate resolution of the complexity of the type inference problem.

# 1 Introduction

One of the outstanding open problems in programming language theory and type theory is the decidability of type inference for the *second order polymorphic typed  $\lambda$ -calculus* invented by Jean-Yves Girard [Gir72] and John Reynolds [Rey74]. More precisely, does there exist an effective procedure which, given an untyped  $\lambda$ -term, can decide whether the term is typable in the Girard/Reynolds system? If so, and the term is typable, can the algorithm produce the required type information?

While this decision problem remains tantalizingly open, we present techniques which can be used to prove significant *lower bounds* on the complexity of type inference for the Girard/Reynolds system, also called  $F_2$ , as well as higher-order extensions  $F_3, F_4, \dots, F_\omega$  proposed by Girard. In particular, we show that recognizing the  $F_2$ -typable terms requires exponential time, and for  $F_\omega$  the problem is nonelementary. We show as well a sequence of lower bounds on recognizing the  $F_k$ -typable terms,  $k$  integer, where the bound for  $F_{k+1}$  is exponentially larger than that for  $F_k$ .

These results are the first nontrivial lower bounds on type inference for the Girard/Reynolds system as well as its higher-order extensions. We hope that the analysis provides important combinatorial insights which will prove useful in the ultimate resolution of the complexity of the type inference problem.

The problem of type inference is one of both theoretical and practical interest. Following the insights of Landin [Lan66], Strachey [Str73], Penrose<sup>1</sup>, and others, the untyped  $\lambda$ -calculus has long been recognized as not merely Turing-complete, but a syntactically natural foundation for the design of programming languages. The process of  $\beta$ -reduction is a simulation of computation and function call, while normal forms correspond to final returned answers.

*Types* augment programming languages with additional guarantees about resultant computational behavior. For instance, *static typing* as in Pascal requires explicit typing by the programmer, but allows all type checking to occur at compile time, with the guarantee that no compiled program will “go wrong” at run time due to type mismatches. The price paid for this guarantee is a loss of *parametric polymorphism* (“code reuse”), so that programs designed for abstract data types must be recoded for each type on which they are used. As an example, the computation of the identity function  $I(x) = x$  is certainly data-independent, yet its realization in Pascal demands identical code with different type declarations for the identity function on integers, booleans, arrays of length 10 of characters, etc.—all this redundancy merely to please the compiler.

A powerful extension to this programming language methodology was proposed by Robin Milner, namely a theory of *type polymorphism* for achieving code reuse, while retaining the benefits of static typing. He gave an algorithm which, presented with an untyped program, could construct the most general type information (known as the *principal type* [Hin69, DM82]) for the program [Mil78]. These insights are implemented in the ML programming language [HMT90] as well as a variety

---

<sup>1</sup>In his 1977 Turing Award lecture, as well as his Foreword to Joseph Stoy’s book on denotational semantics, Dana Scott mentions that it was physicist Roger Penrose who pointed Strachey in the direction of the  $\lambda$ -calculus as a useful device for describing programming language semantics [Sco77, Sto77]. Scott quotes Strachey as having written, “The  $\lambda$ -calculus has been widely used as an aid in examining the semantics of programming languages precisely because it brings out very clearly the connections between a name and the entity it denotes, even in cases where the same name is used for more than one purpose. The earliest suggestion that  $\lambda$ -calculus might be useful in this way that has come to our notice was in a verbal communication from Roger Penrose to [me] in about 1958. At the time this suggestion fell on stony ground and had virtually no influence.” (p. xxiii) [Sto77]

of other functional languages [HW88, Tur85]. The principal type of an ML program provides an important functional specification of the program, describing how it can be used by other programs; as such, types are useful as specifications, and to facilitate incremental compilation. The ML module system is an elegant realization of these basic intuitions.

We view the type system of the ML language as not merely an example of successful software engineering. Because it provides a simplified, yet powerful subset of the polymorphic features inherent in more sophisticated type systems, it has served as an ideal initial subject in the investigation of the computational combinatorics of typed lambda calculi. The “Core ML” language comprising simply typed  $\lambda$ -calculus with polymorphism (as embodied in `let`) enjoys the *strong normalization property*: typable programs are guaranteed to terminate under all reduction strategies.<sup>2</sup> Reconstructing the type of an (untyped) ML expression is thus in essence the synthesis of a termination proof.

Of special interest here is the fact that typable ML expressions are, modulo syntactic sugar, a nontrivial subset of the  $\lambda$ -terms typable in  $F_2, F_3, \dots, F_\omega$ . Furthermore, all of these type systems enjoy strong normalization. Since  $\lambda$ -terms typable in  $F_k$  are also typable in  $F_{k+1}$ , we may regard the higher-order type systems as more and more powerful expression languages in which to encode termination proofs. It is natural to expect that greater expressiveness may facilitate the extraction of stronger lower bounds; proving lower bounds on type inference for  $F_\omega$  should at least be *easier* than for  $F_2$ .

We note, however, that  $F_\omega$  is not simply an esoteric variation on  $F_2$ , since it has been proposed as the mathematical foundation for a new generation of typed functional programming languages, for example Cardelli’s language Quest [Car89], and the language LEAP of Pfenning and Lee [PL89]. The practical use of such languages, however, is considerably hampered by the absence of any type inference algorithm, forcing the programmer into detail and debugging of types as well as of the program. Some arguments have been made that the problem to be solved is *partial* type inference, where the programmer supplies constraints in the form of type information for certain fragments of the program. In view of the undecidability results of Pfenning [Pf88], from a theoretical perspective, it is clear that partial type inference is not easier than pure type inference; in fact, pure type inference might be decidable. Because no progress on (pure) type inference for  $F_2$  and similarly sophisticated typed lambda calculi has seemed possible, there has no doubt been a redirection of research attention elsewhere, where the promise of success has been more encouraging. We intend to refocus attention on type inference by an incremental analysis of its combinatorics, suggesting that there is indeed hope for a better understanding of the problem.

The lower bounds we present on type inference are all proved via *generic reductions*, where an arbitrary TM  $M$  with input  $x$  of length  $n$  is simulated by a  $\lambda$ -term  $\Psi_{M,x}$ , such that  $M$  accepts  $x$  in time  $f(n)$  iff  $\Psi_{M,x}$  is typable. In constructing strong lower bounds, the challenge is to encode as rapidly increasing an  $f(n)$  as possible, while constraining the transducer reducing  $M$  and  $x$  to  $\Psi_{M,x}$  to run in logarithmic space. By the time hierarchy theorem [HS65, HU79], these complexity-class relativized hardness bounds translate (via diagonalization arguments) to nonrelativized bounds. For instance, the  $\text{DTIME}[2^n]$ -hardness bound for typability in  $F_2$  implies a  $\Omega(c^n)$  lower bound for some constant  $c > 1$ .

---

<sup>2</sup>As a consequence, ML is in practice augmented with a set of typed fixpoint operators.

The structure of  $\Psi_{M,x}$  is basically a consequence of the following proposition [KMM91]:

**Proposition 1.1** *Given any strongly normalizing  $\lambda$ -term  $E$ , the problem of determining whether the normal form of  $E$  is first-order typable is  $\text{DTIME}[f(n)]$ -hard, for any total recursive function  $f(n)$ .*

**Proof.** (Sketch) Given a TM  $M$  halting in  $f(n)$  steps on input  $x$  of length  $n$ , construct a  $\lambda$ -term  $\delta$  encoding the transition function of  $M$ , so that if  $y$  codes a machine ID,  $(\delta y)$   $\beta$ -reduces to a  $\lambda$ -term encoding the ID *after* a state transition. Let  $\bar{f}$  be the Church-numeral encoding of  $f$ ,  $\bar{n}$  be the Church numeral for  $n$ , and  $ID_0$  be the encoding of the initial ID. Consider the typing of the normal form of  $E' \equiv \bar{f} \bar{n} \delta ID_0 \triangleright \overline{f(n)} \delta ID_0 \triangleright \delta^{f(n)} ID_0$ , where  $\triangleright$  denotes a sequence of  $\beta$ -reductions. The normal form of  $E'$  codes a machine ID after  $f(n)$  transitions; construct  $E$  (using  $E'$  as a subterm) to force a mistyping in the case of nonacceptance. ■

The fundamental contribution of this paper is to detail what is absent from this proof sketch, strengthening the statement of the proposition to concern the typability of  $E$  (instead of its normal form) in the various systems  $F_k$ , while weakening the proposition by restricting the possible asymptotic growth of  $f(n)$ .<sup>3</sup> The key insight of the lower bound constructions is the understanding of how a sophisticated type system can be used to type terms having long reduction sequences to normal form.

The remainder of the paper details our elaboration on Proposition 1.1, mixed with some short tutorials on the type systems under study, where we have attempted to provide useful and informal intuition along with the usual parcels of formal inference rules. In Section 2, we briefly outline  $F_2$ , the second order polymorphic typed  $\lambda$ -calculus, and in Section 3 we present an exposition of the  $\text{DTIME}[2^{n^k}]$ -hardness bound for typability in  $F_2$ . As corollaries, we present simple proofs of the  $\text{DTIME}[2^{n^k}]$ -completeness of recognizing typable ML programs, as well as an utterly transparent proof that first-order unification is PTIME-complete. The latter is especially perspicuous in that it replaces the ingenious gadgets of [DKM84] with classical combinators from the  $\lambda$ -calculus, and shows how the theorem might have been proved by merely writing a simple, `let`-free ML program.

In Section 4, we provide a description of the systems  $F_3, F_4, \dots, F_\omega$  generalizing  $F_2$ , with emphasis on the significance of *kinds* in these systems. In Section 5 we prove the nonelementary lower bound on typability for  $F_\omega$ , and show the connections between this bound and related lower bounds for the  $F_k$ . Our tutorial material was in many ways inspired by the presentation of [PDM89], which we enthusiastically recommend to anyone desiring a readable introduction to programming in higher-order typed  $\lambda$ -calculi.

---

<sup>3</sup>Observe that these type systems preserve typings under  $\beta$ -reduction, the so-called *subject reduction lemma* [HS86].

## 2 The second order polymorphic typed $\lambda$ -calculus ( $F_2$ )

$F_2$  is best introduced by a canonical example: the identity function. In  $F_2$ , we write the typed polymorphic identity function<sup>4</sup> as  $Id \equiv \Lambda\alpha:*. \lambda\mathbf{x}:\alpha. \mathbf{x}$ . The  $\lambda\mathbf{x}.\mathbf{x}$  should be familiar; the  $\Lambda\alpha:*$  denotes abstraction over *types*<sup>5</sup>. For instance, given a type  $\mathbf{Int}$  encoding integers, we can represent the identity function for integers as:

$$Id [\mathbf{Int}] \equiv (\Lambda\alpha:*. \lambda\mathbf{x}:\alpha. \mathbf{x}) [\mathbf{Int}] \triangleright_{\beta} \lambda\mathbf{x}:\mathbf{Int}. \mathbf{x}$$

The  $\triangleright_{\beta}$  indicates  $\beta$ -reduction at the *type* level, where  $\mathbf{Int}$  is substituted for free occurrences of  $\alpha$  in the body  $\lambda\mathbf{x}:\alpha. \mathbf{x}$ . (We will henceforth use  $\triangleright$  to mean the reflexive, transitive closure of relation defined by  $\triangleright_{\beta}$ .) Given a type  $\mathbf{Bool}$  encoding Boolean values, we may similarly write  $Id [\mathbf{Bool}]$  to get the identity function for booleans. In short,  $Id$  is a *polymorphic* function which may be parameterized with a given type to derive an identity function for that type. We write the type of  $Id$  as  $Id \in \Delta\alpha:*. \alpha \rightarrow \alpha$ , where  $\Delta$  (sometimes written as  $\forall$ ) represents universal quantification over types. Church numerals may be typed in a similar fashion:

$$\begin{aligned} \bar{0} &\equiv \Lambda\alpha:*. \lambda\mathbf{f}:\alpha \rightarrow \alpha. \lambda\mathbf{x}:\alpha. \mathbf{x} \\ \bar{1} &\equiv \Lambda\alpha:*. \lambda\mathbf{f}:\alpha \rightarrow \alpha. \lambda\mathbf{x}:\alpha. \mathbf{f}\mathbf{x} \\ \bar{2} &\equiv \Lambda\alpha:*. \lambda\mathbf{f}:\alpha \rightarrow \alpha. \lambda\mathbf{x}:\alpha. \mathbf{f}(\mathbf{f}\mathbf{x}) \\ &\dots \end{aligned}$$

where the type of all Church numerals is

$$\mathbf{Int} \equiv \Delta\alpha:*. (\alpha \rightarrow \alpha) \rightarrow \alpha \rightarrow \alpha.$$

Here we see how  $\mathbf{Int}$  need not be a built-in ‘‘constant’’ type, but can actually be expressed as the type of Church’s coding of integers. In the untyped  $\lambda$ -calculus, we realize the exponent  $n^m$  by reducing the expression  $(\lambda f. \lambda x. f^m x)$  ( $\lambda f. \lambda x. f^n x$ ) to normal form. The type language of  $F_2$  is sufficiently expressive to type this reduction sequence, given an initial assumption that the two terms are typed as Church numerals of type  $\mathbf{Int}$ :

$$\begin{aligned} &\Lambda\tau:*. (\bar{m} [\tau \rightarrow \tau]) (\bar{n} [\tau]) \\ &\equiv \Lambda\tau:*. ((\Lambda\alpha:*. \lambda\mathbf{f}:\alpha \rightarrow \alpha. \lambda\mathbf{x}:\alpha. \mathbf{f}^m \mathbf{x}) [\tau \rightarrow \tau]) ((\Lambda\alpha:*. \lambda\mathbf{g}:\alpha \rightarrow \alpha. \lambda\mathbf{y}:\alpha. \mathbf{g}^n \mathbf{y}) [\tau]) \\ &\triangleright_{\beta} \Lambda\tau:*. (\lambda\mathbf{f}:(\tau \rightarrow \tau) \rightarrow \tau \rightarrow \tau. \lambda\mathbf{x}:\tau \rightarrow \tau. \mathbf{f}^m \mathbf{x}) (\lambda\mathbf{g}:\tau \rightarrow \tau. \lambda\mathbf{y}:\tau. \mathbf{g}^n \mathbf{y}) \\ &\triangleright_{\beta} \Lambda\tau:*. \lambda\mathbf{x}:\tau \rightarrow \tau. (\lambda\mathbf{g}:\tau \rightarrow \tau. \lambda\mathbf{y}:\tau. \mathbf{g}^n \mathbf{y})^m \mathbf{x} \\ &\triangleright_{\beta} \Lambda\tau:*. \lambda\mathbf{x}:\tau \rightarrow \tau. (\lambda\mathbf{g}:\tau \rightarrow \tau. \lambda\mathbf{y}:\tau. \mathbf{g}^n \mathbf{y})^{m-1} (\lambda\mathbf{y}:\tau. \mathbf{x}^n \mathbf{y}) \\ &\triangleright_{\beta} \Lambda\tau:*. \lambda\mathbf{x}:\tau \rightarrow \tau. (\lambda\mathbf{g}:\tau \rightarrow \tau. \lambda\mathbf{y}:\tau. \mathbf{g}^n \mathbf{y})^{m-2} (\lambda\mathbf{y}:\tau. \mathbf{x}^{n^2} \mathbf{y}) \\ &\dots \\ &\triangleright_{\beta} \Lambda\tau:*. \lambda\mathbf{x}:\tau \rightarrow \tau. \lambda\mathbf{y}:\tau. \mathbf{x}^{n^m} \mathbf{y}. \end{aligned}$$

<sup>4</sup>For clarity, we show expression variables in **boldface** and type variables in *italic* when both occur in the same expression.

<sup>5</sup>For the moment, it seems that the  $*$  is redundant and unnecessary, though in this case, it means that the type variable  $\alpha$  ranges over types. In generalizations of  $F_2$  this notation will become more meaningful, where variables will be able to range over *functions* of types.

Observe that the normal form is also of type  $\text{Int}$ .<sup>6</sup> Hence we might define:

$$\text{expt} \equiv \lambda \bar{m} : \text{Int} . \lambda \bar{n} : \text{Int} . \Lambda \tau : * . (\bar{m} [\tau \rightarrow \tau]) (\bar{n} [\tau])$$

Church numerals are merely polymorphic iteration functions which compose other functions having the same domain and range, while exponentiation is just a higher-order mechanism for constructing such function composers. What happens when we want to compose a function having a *different* domain and range? We will show that the answer to this question is crucial to the development of lower bounds.

## 2.1 Syntax and inference rules of $F_2$

The syntax of  $F_2$  terms is given by the following grammar:

$$\begin{aligned} \mathcal{T} &::= \alpha \mid \mathcal{T} \rightarrow \mathcal{T} \mid \Delta \alpha : * . \mathcal{T} \\ \mathcal{E} &::= x \mid \lambda x : \mathcal{T} . \mathcal{E} \mid \mathcal{E} \mathcal{E} \mid \Lambda \alpha : * . \mathcal{E} \mid \mathcal{E} [\mathcal{T}] \end{aligned}$$

The nonterminals  $\alpha$  and  $x$  range over a set of *type variables* and *expression variables*, respectively, while the nonterminals  $\mathcal{T}$  and  $\mathcal{E}$  define the set of *types* and the set of *expressions*.

Observe that types are either type variables, function types, or quantified types, where we are able to quantify only over type variables. Expressions are either expression variables,  $\lambda$ -abstractions over variables *of type*  $\mathcal{T}$ , function applications of an expression to another expression,  $\Lambda$ -abstractions over *type variables* appearing in an expression (of *kind*  $*$ ; for more details, see Section 4), or applications of an expression to a type (i.e., a *parameterization*, as in the example above of the identity function).

The terms generated from this grammar are sometimes called *raw terms*, and contain a particular subset called the *typed terms*; we think of the latter as the terms that “make sense.” We distinguish this sense of a term by a *type judgement*  $? \vdash e \in \tau$ , read “in context  $?$ , term  $e$  has type  $\tau$ .” Type judgements are derived via a set of *inference rules* characteristic to  $F_2$ ; we adopt the basic presentation of [PDM89].

The first inference rules define a well-formed *context*. A context is a function from a finite domain of expression variables to types. When  $?$  is a context, we write  $?[x:\alpha]$  to mean the function identical to  $?$ , except that its value on  $x$  is  $\alpha$ .

$$\begin{array}{l} (\text{Env-}\langle \rangle) \quad \frac{}{\text{wf}(\langle \rangle)} \\ (\text{Env-term}) \quad \frac{? \vdash \tau \in *}{\text{wf}(?[x:\tau])} \\ (\text{Env-type}) \quad \frac{\text{wf}(?)}{\text{wf}([\alpha: *])} \quad \alpha \notin \text{FV}(?) \end{array}$$

---

<sup>6</sup>Here, we allow  $\alpha$ -renaming of  $\Lambda$ -bound variables at the type level.

The next three rules define the well-formedness of types:

$$\begin{array}{l}
(\textit{Type-var}) \quad \frac{\mathbf{wf}(?)}{? \vdash \alpha \in *} \quad ?(\alpha) = * \\
(\textit{Wff}\rightarrow) \quad \frac{? \vdash \tau \in * \quad ? \vdash \tau' \in *}{? \vdash \tau \rightarrow \tau' \in *} \\
(\textit{Wff}\Delta) \quad \frac{?[\alpha: *] \vdash \tau \in *}{? \vdash \Delta\alpha: *. \tau \in *}
\end{array}$$

The last rules define the well-typedness of expressions, in a syntax-directed fashion:

$$\begin{array}{l}
(\textit{Var}) \quad \frac{? \vdash \tau \in *}{? \vdash x \in \tau} \quad ?(x) = \tau \\
(\rightarrow\textit{-int}) \quad \frac{? \vdash \tau \in * \quad ?[x: \tau] \vdash e \in \tau'}{? \vdash \lambda x: \tau. e \in \tau \rightarrow \tau'} \\
(\rightarrow\textit{-elim}) \quad \frac{? \vdash e \in \tau \rightarrow \tau' \quad ? \vdash e' \in \tau}{? \vdash ee' \in \tau'} \\
(\Delta\textit{-int}) \quad \frac{?[\alpha: *] \vdash e \in \tau}{? \vdash \Lambda\alpha: *. e \in \Delta\alpha: *. \tau} \quad \alpha \notin \mathbf{FV}(?) \\
(\Delta\textit{-elim}) \quad \frac{? \vdash e \in \Delta\alpha: *. \tau' \quad ? \vdash \tau \in *}{? \vdash e[\tau] \in \tau'[\alpha/\tau]}
\end{array}$$

When giving a type judgement in an empty context, we write  $e \in \tau$  rather than  $\langle \rangle \vdash e \in \tau$ . In addition, we adopt the following nonstandard convention: when writing  $F_2$  expressions, expression variables will appear in boldface, while we omit boldface when discussing the *erasure* of types in the expression. For example, in this slight abuse of language, we will write  $\lambda x. x \in \Delta\alpha: *. \alpha \rightarrow \alpha$  as well as  $\Lambda\alpha: *. \lambda \mathbf{x}: \alpha. \mathbf{x} \in \Delta\alpha: *. \alpha \rightarrow \alpha$ .

## 3 An exponential lower bound on $F_2$ type inference

### 3.1 Paradise lost: lessons learned from ML

It has been known for some time that type inference for the simply-typed (first-order)  $\lambda$ -calculus can be solved in polynomial time. A simple and elegant exposition of this fact can be found in [Wan87], where a syntax-directed algorithm is given that transforms an untyped  $\lambda$ -term into a linear sized set of *type equations* of the form  $X = Y$  and  $X = Y \rightarrow Z$ , such that the solution of the equations (via unification [Rob65, PW78]) determines the principal type of the term.

In progressing from this language to ML, it is necessary to understand the effect of quantification over type variables on the complexity of type inference. Naturally, this insight is also crucial in the case of  $F_2$ . The progress in understanding ML quantification and type inference is primarily due to two straightforward observations. The first, given in [Mit90]<sup>7</sup>, is that the following inference rule for

<sup>7</sup>In this survey, the rule is attributed to Albert Meyer. However, it appears as well in the thesis of Luis Damas [Dam85], and in fact a question about it can be found in the 1985 postgraduate examination in computing at Edinburgh University [San88].

`let` preserves exactly the type judgements for closed terms usually derived using the quantification rules:

$$(\text{let}) \frac{? \vdash M \in \tau_0 \quad ? \vdash [M/x]N \in \tau_1}{? \vdash \text{let } x = M \text{ in } N \in \tau_1}$$

Because  $\tau_0$  and  $\tau_1$  are first-order types, this alternate inference rule is a classic instance of quantifier elimination. In the spirit of the Curry-Howard propositions-as-types analogy, it also acts as a sort of cut elimination, preserving propositional theorems at the expense of greatly enlarging the size of the proofs. A proof of this cut elimination theorem appears in the appendix of [KMM91]; a different and much cleaner proof inspired by the Tait strong normalization theorem [Tai67] is found in [Mai92a]. The added *combinatorial* insight comes from that fact that type inference can be completely reduced to first-order unification.

The second observation, due to Paris Kanellakis and John Mitchell, is that `let` can be used to compose functions an exponential number of times with a polynomial-length expression [KM89]:

### Example 3.1

$$\begin{aligned} \Psi \equiv & \text{let } x_0 = \delta \text{ in} \\ & \text{let } x_1 = \lambda y. x_0(x_0 y) \text{ in} \\ & \text{let } x_2 = \lambda y. x_1(x_1 y) \text{ in} \\ & \dots \\ & \text{let } x_t = \lambda y. x_{t-1}(x_{t-1} y) \text{ in } x_t \end{aligned}$$

The above expression `let`-reduces to  $\lambda y. \delta^{2^t} y$ , where the occurrences of  $\delta$  are *polymorphic* — each occurrence has a different type.

The significance of this polymorphism is exploited in the lower bound of [Mai90, KMM91], where it is shown that recognizing typable ML expressions of length  $n$  can be solved in  $\text{DTIME}[2^n]$ , and is  $\text{DTIME}[2^{n^k}]$ -hard for every integer  $k \geq 1$  under logspace reduction.<sup>8</sup> The lower bound is a generic reduction: given a TM  $M$  accepting or rejecting its input  $x$  of length  $n$  in at most  $2^{n^k}$  steps, we construct an ML term  $\Phi_{M,x}$  using a logspace transducer, where  $M$  accepts  $x$  iff  $\Phi_{M,x}$  is typable. We expand further on this proof technique in this section, extending its application to more powerful type systems.

The coding of the TM computation sketched above is embedded in the putative *typing* of  $\Phi_{M,x}$ , rather than in its *value*. The simulation of the TM is based on the observation that the transition function of  $M$  is merely a Boolean circuit computing state, head movement, and what to write on the tape, combined with rudimentary list processing to manipulate the left and right hand sides of the tape. The details of the proof show that these basic operations can be simulated by first-order unification problems which may be induced via the typing of `let`-free  $\lambda$ -terms. If  $\delta$  is indeed the ML term simulating the transition function, and  $ID_0$  codes the initial ID of the TM, then the type of  $\Psi ID_0$  codes the ID of the TM after  $2^t$  state transitions. Taking  $t = n^k$ , we can then construct an ML expression  $E$  containing  $\Psi ID_0$  as a subterm, where the type of  $E$  necessarily codes whether  $M$  rejected  $x$ .

---

<sup>8</sup>An alternate proof, based on the analysis of a problem called *acyclic seminunification*, is found in [KTU90].

Using the methods of [DKM84] for coding Boolean logic, the simulation codes the Boolean values *true* and *false* as:<sup>9</sup>

$$\begin{aligned} \text{true} &\equiv \lambda x.\lambda y.\lambda z.K z (Eq x y) \in \Delta a:*. \Delta b:*. a \rightarrow a \rightarrow b \rightarrow b \\ \text{false} &\equiv \lambda x.\lambda y.\lambda z.z \in \Delta a:*. \Delta b:*. \Delta c:*. a \rightarrow b \rightarrow c \rightarrow c \end{aligned}$$

where

$$Eq \equiv \lambda x.\lambda y.K x (\lambda z.K (zx)(zy)) \in \Delta a:*. a \rightarrow a \rightarrow a$$

As a consequence, if the types of ML expressions  $P$  and  $Q$  cannot be unified, we know *true*  $PQ$  cannot be typed, while *false*  $PQ$  can be typed: *true* is a function insisting that its two arguments have the same type, while *false* makes no such restriction.

In its nascent state, the ML lower bound is useless to bound the complexity of  $F_2$  type inference. The proof of “machine accepts iff ML expression types” is made by a straightforward appeal to the simple logic of first-order unification: the proof construction computes a Boolean value coding the answer to “Did  $M$  reject its input?” and uses the value, as described above, to force a first-order mistyping when the answer is *true*. To further claim that there is no  $F_2$  typing is far from clear, since unlike ML,  $F_2$  does not admit naive quantifier elimination, where an ML expression involving **let** is typable iff a similar, **let**-free expression is typable. Because of this equivalence, we see that arguments about typability based on first-order unification are simply too weak. Proving that strongly normalizing terms are not  $F_2$ -typable is very difficult: as evidence, we point merely to the tremendous effort of Giannini and Ronchi della Rocca [GR88] in their identifying a single, simple, strongly normalizing term which is not  $F_2$ -typable. The Giannini-Ronchi results are an indication that  $F_2$  type inference might in fact be decidable, since they achieved a separation between  $F_2$ -typable terms and the r.e.-complete class of strongly normalizable terms. However, the techniques they employ require such overwhelming computational detail, and provide so little large-scale insight, that they seem virtually useless for showing whether or not the term we have constructed is  $F_2$ -typable.

### 3.2 Paradise regained: an $F_2$ lower bound

The force of the ML argument can be regained, however, by changing the simulation of Boolean logic from that found in [DKM84] to the classic simulation in the  $\lambda$ -calculus. For example, we type the Boolean values as:

$$\begin{aligned} \text{true} &\equiv \Lambda \alpha:*. \Lambda \beta:*. \lambda \mathbf{x}:\alpha. \lambda \mathbf{y}:\beta. \mathbf{x} \\ &\in \Delta \alpha:*. \Delta \beta:*. \alpha \rightarrow \beta \rightarrow \alpha \\ \text{false} &\equiv \Lambda \alpha:*. \Lambda \beta:*. \lambda \mathbf{x}:\alpha. \lambda \mathbf{y}:\beta. \mathbf{y} \\ &\in \Delta \alpha:*. \Delta \beta:*. \alpha \rightarrow \beta \rightarrow \beta \end{aligned}$$

We remark that this encoding is *not* Girard’s inductive-type definition of Boolean values; observe simply that *true* and *false* have different types, while in Girard’s construction, the Boolean values are both terms of type  $\Delta \alpha:*. \alpha \rightarrow \alpha \rightarrow \alpha$ .

---

<sup>9</sup>We use the syntax of  $F_2$  types to give typings of ML terms, observing that ML types are merely outermost-quantified *first-order* (i.e., quantifier-free) types. Such types are a proper subset of the  $F_2$  types, where *any* subterm of a type may contain quantifiers.

By using this well-known coding of classical logic (see, e.g., [HS86]), we discover a new class of directed acyclic graphs realizing Boolean operations via first-order unification, in the style of [DKM84]. Moreover, the analysis of these graphs allows us to view types as explicit codings of certain reduction sequences in the  $\lambda$ -calculus. As a consequence, we derive a new and simplified proof that first-order unification is PTIME-complete, which is particularly striking since it shows how that theorem could have been proved by writing a very simple `let`-free ML program using the classic coding of Boolean logic. By generalizing the realization of Boolean logic to the realization of *any* functions on finite domains, we derive a new and simpler proof of the  $\text{DTIME}[2^{n^k}]$ -hardness of recognizing typable ML expressions.

Finally, by a slight augmentation of the ML proof, we derive a  $\text{DTIME}[2^{n^k}]$ -hardness bound on the recognition of  $F_2$ -typable terms. We make essential and powerful use of the strong normalization theorem for  $F_2$  [Gir72, GLT89, Gal90], using the coded Boolean answer  $A$  to the question “Did machine  $M$  reject its input of length  $n$  in  $2^{n^k}$  steps?” to *choose* between a trivial terminating computation and a clearly nonterminating one:

$$\Psi \equiv (\lambda x.xx)(A (\lambda x.x) (\lambda y.yy))$$

Observe that if  $A \triangleright \text{false}$ , then  $\Psi \triangleright (\lambda x.xx)(\lambda y.yy)$ ; since  $\Psi$  is not normalizable, it is not typable. The difficult technical question then becomes to show that if the TM accepts, then  $\Psi$  can be typed. In this case, we will have to look more carefully at the structure of the term  $A$ .

### 3.3 Encoding Boolean logic by terms and types

Using the definitions of *true* and *false* from the previous section, we can type the usual codings of Boolean functions as:

$$\begin{aligned} \text{and} &\equiv \Lambda\alpha:*. \Lambda\beta:*. \Lambda\gamma:*. \Lambda\delta:*. \\ &\quad \lambda\mathbf{p}:\alpha \rightarrow (\beta \rightarrow \gamma \rightarrow \gamma) \rightarrow \delta. \lambda\mathbf{q}:\alpha. \mathbf{p} \ \mathbf{q} \ (\text{false} \ [\beta][\gamma]) \\ &\quad \in \Delta\alpha:*. \Delta\beta:*. \Delta\gamma:*. \Delta\delta:*. \\ &\quad (\alpha \rightarrow (\beta \rightarrow \gamma \rightarrow \gamma) \rightarrow \delta) \rightarrow \alpha \rightarrow \delta \\ \text{or} &\equiv \Lambda\alpha:*. \Lambda\beta:*. \Lambda\gamma:*. \Lambda\delta:*. \\ &\quad \lambda\mathbf{p}:(\alpha \rightarrow \beta \rightarrow \alpha) \rightarrow \gamma \rightarrow \delta. \lambda\mathbf{q}:\gamma. \mathbf{p} \ (\text{true} \ [\alpha][\beta]) \ \mathbf{q} \\ &\quad \in \Delta\alpha:*. \Delta\beta:*. \Delta\gamma:*. \Delta\delta:*. \\ &\quad ((\alpha \rightarrow \beta \rightarrow \alpha) \rightarrow \gamma \rightarrow \delta) \rightarrow \gamma \rightarrow \delta \\ \text{not} &\equiv \Lambda\alpha:*. \Lambda\beta:*. \Lambda\gamma:*. \Lambda\delta:*. \Lambda\epsilon:*. \\ &\quad \lambda\mathbf{p}:(\alpha \rightarrow \beta \rightarrow \beta) \rightarrow (\gamma \rightarrow \delta \rightarrow \gamma) \rightarrow \epsilon. \\ &\quad \mathbf{p} \ (\text{false} \ [\alpha][\beta]) \ (\text{true} \ [\gamma][\delta]) \\ &\quad \in \Delta\alpha:*. \Delta\beta:*. \Delta\gamma:*. \Delta\delta:*. \Delta\epsilon:*. \\ &\quad ((\alpha \rightarrow \beta \rightarrow \beta) \rightarrow (\gamma \rightarrow \delta \rightarrow \gamma) \rightarrow \epsilon) \rightarrow \epsilon \end{aligned}$$

Observe that all of these typings can be derived by the ML type inference algorithm. As in ML, all the types are outermost quantified, although we have written the typings in the notational style

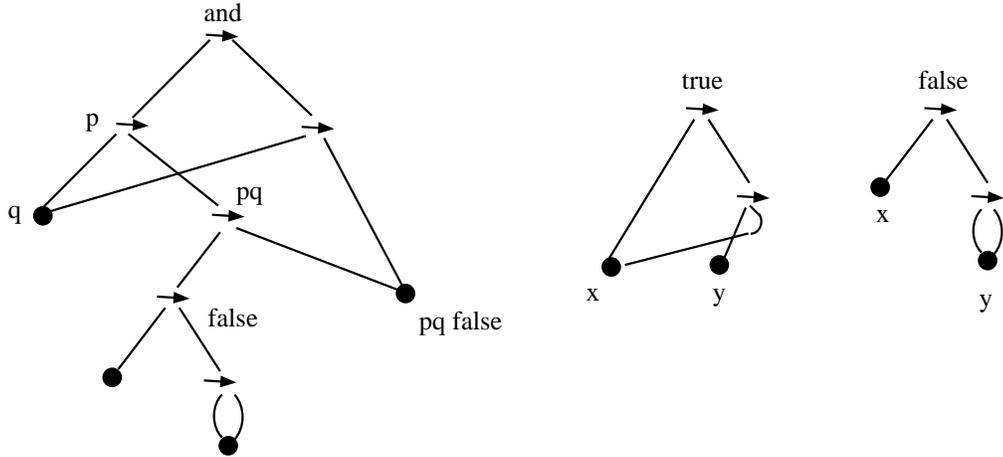

Figure 1: Graph representations of *and*, *true*, *false*

of  $F_2$ . The subterms *true* and *false* are explicitly parameterized to ensure that the terms are well-typed; in this manner, the typing rules of  $F_2$  are used to simulate the unification mechanism of the ML type inference algorithm.

The computational significance of these typings is not particularly lucid as written. We can however clarify this significance by picturing the types as directed acyclic graphs (dags), having nodes labelled with appropriate subterms. For example, Figure 1 shows the typing of *and* drawn as a graph, together with the dags for *true* and *false*. At the level of pure  $\lambda$ -terms, we know that the defined terms simulate Boolean logic, but Figure 1 shows how the simulation is effected as well at the level of first-order unification and types. For instance, we know that *and true q* should reduce to *q*, and that *and false q* should reduce to *false*. To simulate the former reduction, we unify the dag rooted at *p* (the “first input”) with the dag representing the type of *true*, causing the node labelled *q* to be unified with the “output node” labelled *p q false*, so that the *type* of input *q* is indeed the type of *and true q*. To simulate the reduction of *and false q*, observe that unification of “input” *p* with the dag representing the type of *false* causes the substructure of the graph for *and* rooted at the node labelled *false* to be unified with the output node. Then the value and the type of the “second input” *q* become irrelevant to the final output.

Similar arguments can be made that the definitions of *or* and *not* function properly at the level of reductions in the untyped  $\lambda$ -calculus, and the types of these definitions simulate logic faithfully at the level of first-order unification. Figure 2 shows the relevant dags coding the types of *or* and *not*.

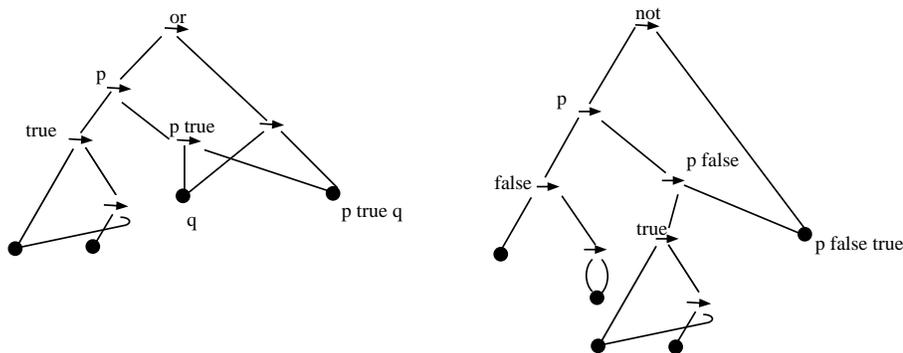

Figure 2: Graph representations of *or*, *not*.

### 3.4 Unification is PTIME-complete

The graphs depicted in Figures 1 and 2 have the same computational significance as the gadgets invented by Dwork, Kanellakis, and Mitchell in their well-known proof that unification is complete for deterministic polynomial time [DKM84]. In this section, we show how their theorem could have been proved by writing an ML program using the classic  $\lambda$ -calculus encodings of the logical operations. The insight provided by this simpler problem is important in understanding the more detailed and sophisticated arguments we will see later on.

The proof of [DKM84] was, essentially, that the *circuit value problem* (given a Boolean circuit with inputs, what is its output?) could be reduced to unification. The circuit value problem is logspace complete for polynomial time [Lad75], since any polynomial time TM computation can be described by a polynomial sized circuit, where the input to the circuit is the initial tape contents, and polynomial “layers” of circuitry implement each state transition.

To carry out the simulation of a Boolean circuit in ML, we define (as above):<sup>10</sup>

```

- fun True x y= x;
val True = fn : 'a -> 'b -> 'a
- fun False x y= y;
val False = fn : 'a -> 'b -> 'b
- fun And p q= p q False;
val And = fn : ('a -> ('b -> 'c -> 'c) -> 'd) -> 'a -> 'd
- fun Or p q= p True q;
val Or = fn : (('a -> 'b -> 'a) -> 'c -> 'd) -> 'c -> 'd
- fun Not p= p False True;
val Not = fn : (('a -> 'b -> 'b) -> ('c -> 'd -> 'c) -> 'e) -> 'e

```

<sup>10</sup>To avoid conflict with ML reserved words, examples using ML capitalize the names of declared functions.

When these Boolean functions are used, notice that they output functions as values; moreover, the principal types of these functions identify them uniquely as `True` or `False`:

```
- Or False True;
val True = fn : 'a -> 'b -> 'a
- And True False;
val False = fn : 'a -> 'b -> 'b
- Not True;
val False = fn : 'a -> 'b -> 'b
```

As a consequence, while the compiler does not *explicitly* reduce the above expressions to normal form, hence computing an “answer,” its type inference mechanism implicitly carries out that reduction to normal form, expressed in the language of first-order unification.

We now introduce pairing and fanout:

```
- fun Pair x y= fn z=> z x y;
val Pair = fn : 'a -> 'b -> ('a -> 'b -> 'c) -> 'c
- fun Fanout p= p (Pair True True) (Pair False False);
val Fanout = fn : (((('a -> 'b -> 'a) -> ('c -> 'd -> 'c) -> 'e) -> 'e)
-> ((('f -> 'g -> 'g) -> ('h -> 'i -> 'i) -> 'j) -> 'j) -> 'k) -> 'k
```

The importance of `Fanout`, as in [Mai90, KMM91], is that it produces two copies of a logic value which do not share type variables.

```
- Fanout True;
val it = fn : (('a -> 'b -> 'a) -> ('c -> 'd -> 'c) -> 'e) -> 'e
- Fanout False;
val it = fn : (('a -> 'b -> 'b) -> ('c -> 'd -> 'd) -> 'e) -> 'e
```

We code circuits so that every Boolean value is used *exactly once*. An intuitive correspondence to *linear logic* should be immediately apparent, in that the described simulation of logic breaks down if a Boolean value is used as an input to two different computations. For example, if we define `fun Break p= Or p (Not p)`, we find, rather peculiarly, that `Break True` has type `'a -> 'a -> 'a`, a type that is the most general unifier (least upper bound, in the lattice of unification) of the types of `True` and `False`. The function `break` uses input `p` in two different contexts, and each context imposes constraints on the (monomorphic) type. As a consequence, the output no longer uniquely codes a Boolean value.

To facilitate the understanding of our coding, we introduce some syntactic sugar for pattern matching, introducing the use of semicolon (;) to simulate a notion of sequentiality. We write  $\langle v_1, \dots, v_k \rangle = \psi; \phi$  for  $\psi(\lambda v_1. \dots \lambda v_k. \phi)$ . For example,  $\langle p, q \rangle = \text{fanout } r; \phi$  should be read as “fanout Boolean value  $r$ , making two copies  $p$  and  $q$ , and in that context return the value of  $\phi$ .” We write  $r = \text{op } pq; \phi$  for  $(\lambda r. \phi)(\text{op } pq)$  and  $r = \text{op } p; \phi$  for  $(\lambda r. \phi)(\text{op } p)$  for binary and unary operators, respectively. The ; is meant to be right associative, so that  $\phi_1; \phi_2; \phi_3$  means  $\phi_1; (\phi_2; \phi_3)$ .

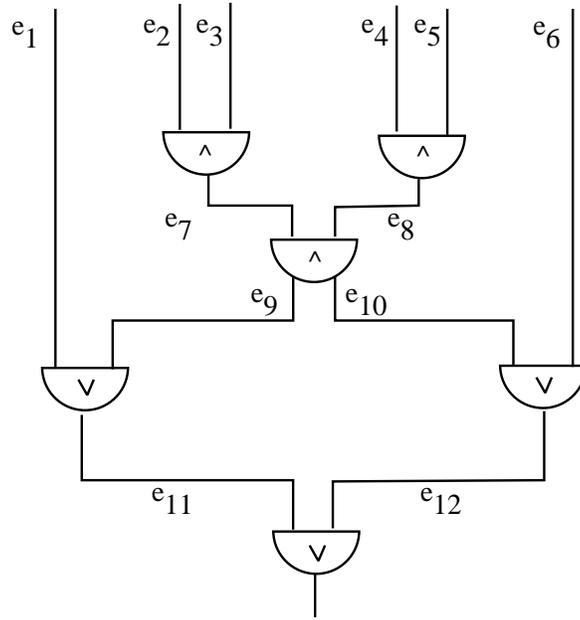

Figure 3: Labelling of a Boolean circuit

A Boolean circuit can now be coded as a  $\lambda$ -term by labelling its (wire) edges and traversing them bottom-up, inserting logic gates and fanout gates appropriately. We consider the circuit example from ([DKM84], p. 43), pictured in Figure 3; the circuit is realized by the code

$$\lambda e_1.\lambda e_2.\lambda e_3.\lambda e_4.\lambda e_5.\lambda e_6.$$

$$e_7 = \text{and } e_2 \ e_3;$$

$$e_8 = \text{and } e_4 \ e_5;$$

$$\langle e_9, e_{10} \rangle = \text{fanout } (\text{and } e_7 \ e_8);$$

$$e_{11} = \text{or } e_1 \ e_9;$$

$$e_{12} = \text{or } e_{10} \ e_6;$$

$$\text{or } e_{11} \ e_{12}$$

Removing the syntactic sugar, this straight-line code “compiles” to the slightly less comprehensible

```

- fun circuit e1 e2 e3 e4 e5 e6=
(fn e7=>
  (fn e8=>
    (Fanout (And e7 e8))
    (fn e9=> fn e10=>
      (fn e11=>
        (fn e12=> Or e11 e12)
        (Or e10 e6))
        (Or e1 e9)))
    (And e4 e5))
  (And e2 e3);

val circuit = fn : (('a -> 'b -> 'a) -> 'c -> ('d -> 'e -> 'd) -> 'f
-> 'g) -> ('h -> ('i -> 'j -> 'j) -> 'k -> ('l -> 'm -> 'm) -> (((('n
-> 'o -> 'n) -> ('p -> 'q -> 'p) -> 'r) -> 'r) -> (((('s -> 't -> 't)
-> ('u -> 'v -> 'v) -> 'w) -> 'w) -> ('c -> (('x -> 'y -> 'x) -> 'z ->
'f) -> 'g) -> 'ba) -> 'h -> ('bb -> ('bc -> 'bd -> 'bd) -> 'k) -> 'bb
-> 'z -> 'ba

```

The type of `circuit` is the equivalent of the construction in [DKM84] of the circuit as a unification structure. We can compute circuit values by instantiating the inputs appropriately, for instance:

```

- circuit False True True True True False;
val it = fn : 'a -> 'b -> 'a

```

Observe that this evaluation produces both the correct type, and the correct value: there is of course only one closed  $\lambda$ -term in normal form with the given type, namely  $true \equiv \lambda x.\lambda y.x$ . The computation of the value is performed by the interpreter, while that of the type is performed by the compiler, yet both are essentially the same. In essence, we have forced the compiler—more specifically, the type inference mechanism—into doing computation typically carried out by the interpreter. It should be clear that any Boolean circuit can be transformed into such a  $\lambda$ -term. In mundane programming language terminology, the complexity theoretic *reduction* is merely a *compiler*. The size of the  $\lambda$ -term is clearly linear in the size of the circuit, and the transformation described can be effected in polynomial time. Observe that polynomial space is required by this translation scheme, since output wire names (for example, `e7`) are output by the transducer while their *values* (for example, `And e2 e3`) are pushed on a stack for subsequent output. The size of the stack can clearly be linear in the size of the ML program output by the transducer.

We can in fact carry out this sort of reduction in logarithmic space, curiously, by coding computation in a continuation-passing style. A hint towards carrying out such a reduction is given by the use of the `Fanout` gate in the above example, where `Fanout` takes input `And e7 e8`, and produces two outputs packaged together as a pair. The pair is then applied to the continuation (`fn e9=> fn e10=> . . .`), so that the two (duplicate) truth values in the pair are bound to `e9` and `e10`. It is a simple matter to treat the single-output cases similarly, by coding a continuation-passing version of unary and binary logical functions:

```

- fun cp1 fnc p k= k (fnc p);
val cp1 = fn : ('a -> 'b) -> 'a -> ('b -> 'c) -> 'c
- cp1 Not;
val it = fn :
((('a -> 'b -> 'b) -> ('c -> 'd -> 'c) -> 'e) -> ('e -> 'f) -> 'f
- fun cp2 fnc p q k= k (fnc p q);
val cp2 = fn : ('a -> 'b -> 'c) -> 'a -> 'b -> ('c -> 'd) -> 'd

```

Now we use the CPS-version of the logic gates, in a style very much like straight-line code or machine language:

```

- fun circuit e1 e2 e3 e4 e5 e6=
  (cp2 And) e2 e3 (fn e7=>
  (cp2 And) e4 e5 (fn e8=>
  (cp2 And) e7 e8 (fn f=>
  Fanout f (fn e9=> fn e10=>
  (cp2 Or) e1 e9 (fn e11=>
  (cp2 Or) e10 e6 (fn e12=>
  Or e11 e12))))));
val circuit = fn : (('a -> 'b -> 'a) -> 'c -> ('d -> 'e -> 'd) -> 'f
-> 'g) -> ('h -> ('i -> 'j -> 'j) -> 'k -> ('l -> 'm -> 'm) -> (((('n
-> 'o -> 'n) -> ('p -> 'q -> 'p) -> 'r) -> 'r) -> (((('s -> 't -> 't)
-> ('u -> 'v -> 'v) -> 'w) -> 'w) -> ('c -> (('x -> 'y -> 'x) -> 'z ->
'f) -> 'g) -> 'ba) -> 'h -> ('bb -> ('bc -> 'bd -> 'bd) -> 'k) -> 'bb
-> 'z -> 'ba

- circuit False True True True True False;
val it = fn : 'a -> 'b -> 'a

```

The style of this coding is very similar to that used by Mitchell Wand in a framework for verifying compilers, where assembly code is generated in a version of  $\lambda$ -calculus [Wan92]; the idea also appears in [AJ89, KH89]. A trivial analysis shows this translation scheme to be a logarithmic space reduction, since the transducer need only *count* right parentheses to be output at the end of the expression, instead of storing expressions on a stack. In this analysis, we have also assumed that the wire names have length logarithmic in the size of the circuit.

### 3.5 Coding functions with finite domains

The coding techniques used in the previous section make no particular use of the fact that the functions simulated are logical ones. On the contrary, the essential feature of the coding is that the Boolean functions are over finite domains and ranges. As a consequence, we may generalize the construction to any function with this characteristic.

Given a finite set  $E^k = \{e_1^k, \dots, e_k^k\}$ , we code the  $i$ -th element  $e_i^k$  by the  $\lambda$ -term

$$d_i^k \equiv \lambda x_1. \lambda x_2. \dots \lambda x_k. x_i.$$

A  $t$ -tuple  $\vec{e} \equiv \langle e_1, \dots, e_t \rangle$  is coded by the  $\lambda$ -term  $\lambda z. z e_1 \dots e_t$ ; note  $\vec{e} d_i^t \triangleright e_i$ , where  $\triangleright$  is the reflexive, transitive closure of the basic reduction step denoted by  $\triangleright_\beta$ . A function  $m: E^k \rightarrow F$  with finite

domain can then be coded as the tuple

$$\vec{m} = \langle m(e_1), \dots, m(e_k) \rangle,$$

so that  $\vec{m}d_i^k \triangleright m(e_i)$ . When the finite domain of a function is the product of several finite sets, we realize the function in its curried form.

In this manner, we can code the Boolean functions in tabular form: recalling  $true \equiv \lambda x.\lambda y.x$  and  $false \equiv \lambda x.\lambda y.y$ , we have

$$\begin{aligned} not &\equiv \langle false, true \rangle \\ and &\equiv \langle \langle true, false \rangle, \langle false, false \rangle \rangle \\ or &\equiv \langle \langle true, true \rangle, \langle true, false \rangle \rangle \end{aligned}$$

Again, the codings work simultaneously at the value level and at the type level; they are moreover ML-typable. Observe that the “currying” trick of nested tuples is used for the binary operations.

### 3.6 Encoding Turing Machines by lambda terms

Given a deterministic TM  $M$ , we show how to encode the transition function of  $M$  as a  $\lambda$ -term  $\delta$  such that if  $ID$  is a  $\lambda$ -term encoding a configuration of  $M$ , and  $ID'$  is the next configuration of  $M$  coded as a  $\lambda$ -term, then  $\delta ID \triangleright ID'$ . We call this a simulation *at the value level*. In Section 3.7, we will see that the type of  $\delta$  also encodes a simulation at the type level. The encoding, which uses the methods of the previous section, also yields a very compact and simple proof of the  $\text{DTIME}[2^{n^k}]$ -hardness bound for recognizing ML-typable terms. To reduce notational clutter, we blur the name distinctions between parts of the TM and their respective codings in the  $\lambda$ -calculus; for example, we write  $q_i$  for a TM state as well as its coding as a  $\lambda$ -term.

Since the TM manipulates a tape (represented as two lists, to the left and right of the read head), we need to code lists and relevant operations on them, while preserving the symmetry of values and types. Therefore, a *list*  $[x_1, \dots, x_k]$  denotes the tuple  $\langle x_1, \langle x_2, \dots, \langle x_k, \text{nil} \rangle \dots \rangle \rangle$ , where  $\text{nil} \equiv \lambda z.z$ .

Let  $M$  have finite states  $Q = \{q_1, \dots, q_k\}$  with initial state  $q_1$  and final states  $F \subset Q$ ; tape alphabet  $C = \{c_1, \dots, c_\ell\}$  with blank symbol  $\flat \equiv c_1$ ; tape head movements  $D = \{d_1, d_2, d_3\}$  (left, no movement, right); and transition table  $\partial: Q \rightarrow C \rightarrow Q \times C \times D$ .<sup>11</sup> A *configuration* (ID) of  $M$  is a triple  $\langle q, L, R \rangle \in Q \times C^* \times C^*$  giving the state and contents of the left and right hand sides of the tape; we thus define the transition function of  $M$  by the usual extension of  $\partial$ . We assume that the TM never writes a blank, that it does not move its tape head iff it reads a blank, and that it never runs off the left end of the tape.

Using techniques of the previous section, we code each state  $q_i$  as the projection function  $\lambda x_1.\lambda x_2.\dots.\lambda x_k.x_i$ , each tape symbol  $c_i$  as  $\lambda x_1.\lambda x_2.\dots.\lambda x_\ell.x_i$ , and head movement  $d_i$  as  $\lambda x_1.\lambda x_2.\lambda x_3.x_i$ . If  $\partial q_i c_j = t_{i,j}$  for some  $t_{i,j} = \langle q, c, d \rangle \in Q \times C \times D$ , then the map can be coded by the  $\lambda$ -term

$$\partial \equiv \langle \langle t_{1,1}, t_{1,2}, \dots, t_{1,\ell} \rangle, \langle t_{2,1}, t_{2,2}, \dots, t_{2,\ell} \rangle, \dots, \langle t_{k,1}, t_{k,2}, \dots, t_{k,\ell} \rangle \rangle;$$

observe  $\partial q_i c_j \triangleright t_{i,j}$ .

---

<sup>11</sup>Note that we choose to represent  $\partial$  in its curried form, rather than of type  $\partial: Q \times C \rightarrow Q \times C \times D$ .

We represent a TM ID by a tuple  $\langle q, \mathbf{L}, \mathbf{R} \rangle$ , where  $\mathbf{L} \equiv [\ell_1, \dots, \ell_m]$  and  $\mathbf{R} \equiv [r_1, \dots, r_n]$  are lists coding the left and right contents of the tape; we assume the tape head is reading  $r_1$ , and  $\ell_1$  is the cell contents to the immediate left.

Recalling the pattern-matching notation we have introduced in Section 3.4, the transition function of  $M$  has a very simple encoding:

$$\begin{aligned} \delta &\equiv \lambda ID. \langle q, \mathbf{L}, \mathbf{R} \rangle = ID; \\ &\quad \langle \ell, L \rangle = \mathbf{L}; \\ &\quad \langle r, R \rangle = \mathbf{R}; \\ &\quad \langle q', c', d' \rangle = \partial q r; \\ &\quad d' \langle q', L, \langle \ell, \langle c', R \rangle \rangle \\ &\quad \quad \langle q', \langle \ell, L \rangle, \langle c', \langle \flat, \text{nil} \rangle \rangle \rangle \\ &\quad \quad \langle q', \langle c', \langle \ell, L \rangle \rangle, R \rangle \end{aligned}$$

Notice that when the read head does not move, the ID  $\langle q', \langle \ell, L \rangle, \langle c', \langle \flat, \text{nil} \rangle \rangle$  is chosen; in this case, we know by the definition of the TM that a blank has been read, and the read head has therefore reached its *rightmost* position, where there should be an infinite sequence of blank cells to the right. This infinite sequence is not coded explicitly, but rather simulated implicitly by constructing a new right hand side of the tape, namely  $\langle c', \langle \flat, \text{nil} \rangle \rangle$ ; we have “tacked on” another blank cell. Should the TM move again to the right, the process will be repeated. We remark that even though the TM can write several different values in a tape cell over time, the simulation of this behavior manufactures a *new* coding of the cell each time the tape position is traversed, and uses list processing to place the cell in the correct position on the tape. In this way, no representation of a cell is ever used more than once.

We also observe that  $\langle q', c', d' \rangle$  codes the state, symbol written, and head direction for the next machine configuration, as computed by  $\partial$ ; the term  $d'$  is then used *as a projection function* to choose the  $\lambda$ -term coding the next configuration. Because no value is “used” more than once, no side-effecting of type variables occurs, and the fanout gates mentioned earlier, used in the proofs in [Mai90, KMM91], are not necessary.

### 3.7 Encoding Turing Machines by types

The simple encoding  $\delta$  of the transition function is typable in ML; moreover, it has the following property:

**Proposition 3.2** *Let  $ID$  and  $ID'$  be  $\lambda$ -terms coding successive configurations of  $M$ , and let  $\sigma$  and  $\sigma'$  be their respective first-order principal types. Then  $\delta ID \triangleright ID'$ , and  $\delta ID \in \sigma'$ . Furthermore, if  $ID_k$  is a  $\lambda$ -term with principal type  $\sigma^k$  coding the state of  $M$  after  $k$  transitions from  $ID$ , then  $(\bar{k} \delta) ID \triangleright ID_k$ , and  $(\bar{k} \delta) ID \in \sigma^k$ .*

**Proof.** Before proceeding with details of the proof, the statement of this important Proposition deserves further explanation. It claims that the computation of TM  $M$  is simulated not only at the *value* level, but also at the *type* level. The first part of the Proposition, dealing with successive

machine configurations, asserts this dual representation purely in the type system of ML, and by extension, in  $F_2$ .

The following commutative diagram summarizes this duality:

Figure: Duality of ID representation via types and terms.

In typing  $\delta ID$ , first-order unification is performed on the principal types of  $\delta$  and  $ID$ , producing a most general typing of  $\delta ID$ . The unification is merely a complicated variant of the calculation seen in Sections 3.3 and 3.4, where unification simulated Boolean calculations; in the case of the Proposition, unification simulates calculations of finite functions specified by the transition map of the TM.

The second part of the Proposition, concerning the coding of multiple transitions of the TM, makes a similar assertion, but *not* purely in the type system of ML—essential use is made of the added expressibility of  $F_2$  types. Given that  $\delta ID$  can indeed be typed, how can the typing technology be extended to type, say,  $\delta(\delta(\delta(\delta ID)))$ ?

The answer is simple: each instance of  $\delta$  is typed *differently*. Each such typing is indeed an instance of the principal type of  $\delta$ , but changes according to the type of its argument. The key idea implicit in this construction is the composition of functions having different domains and ranges.

We are certainly familiar with composing functions of type  $\text{Int} \rightarrow \text{Int}$ , for example, while a function of type  $\text{Int} \rightarrow \text{Bool}$  cannot be so composed with itself. However, in the case of polymorphic functions where the range can be *parameterized* to have the same structure as the domain, we may in fact carry out such function composition. Rather than examining the fairly complicated type of  $\delta$ , we consider as a motivating example the polymorphic composition of the Boolean function *not*.

We begin by carrying out the composition in ML:

```

- val Not= Pair False True;
val Not = fn : (('a -> 'b -> 'b) -> ('c -> 'd -> 'c) -> 'e) -> 'e
- Not True;
val it = fn : 'a -> 'b -> 'b
- Not False;
val it = fn : 'a -> 'b -> 'a
- fun Notnot p= Not (Not p);
val Notnot = fn : (('a -> 'b -> 'b) -> ('c -> 'd -> 'c) ->
('e -> 'f -> 'f) -> ('g -> 'h -> 'g) -> 'i) -> 'i

- Notnot True;
val it = fn : 'a -> 'b -> 'a
- Notnot False;
val it = fn : 'a -> 'b -> 'b

```

In  $F_2$ , `Notnot` can be defined as:

$$\begin{aligned}
\text{notnot} &= \Lambda\alpha:*. \Lambda\beta:*. \Lambda\gamma:*. \Lambda\delta:*. \Lambda\epsilon:*. \Lambda\phi:*. \Lambda\xi:*. \Lambda\eta:*. \Lambda\iota:*. \\
&\quad \lambda\mathbf{p}:((\alpha \rightarrow \beta \rightarrow \beta) \rightarrow (\gamma \rightarrow \delta \rightarrow \gamma) \rightarrow (\epsilon \rightarrow \phi \rightarrow \phi) \rightarrow (\xi \rightarrow \eta \rightarrow \xi)) \rightarrow \iota. \\
&\quad \text{not } [\epsilon][\phi][\xi][\eta][\iota] \\
&\quad (\text{not } [\alpha][\beta][\gamma][\delta][(\epsilon \rightarrow \phi \rightarrow \phi) \rightarrow (\xi \rightarrow \eta \rightarrow \xi) \rightarrow \iota] \mathbf{p})
\end{aligned}$$

In Figure 2, the type of `not` is depicted as a dag. Even though we think of `not` as a function on the “type” of Booleans, we have already remarked that our codings of `true` and `false` are not of Boolean type in the standard inductive sense. Furthermore, the right hand side of the dag, a single node, clearly has less structure than the left hand side. In fact, we can instantiate the right hand side to look like the left hand side, as shown in Figure 4, to construct a type for `notnot`. The  $F_2$  code for `notnot` contains type information that syntactically reproduces the information in the graph of Figure 4. Notice that the outermost `not` in the  $F_2$  code corresponds to the *deeper* graph for `not` in the figure.

Observe what happens when the dag rooted at  $p$  is unified with the dag for `true`: the leftmost `false` in Figure 4 is forced to unify with the dag rooted at  $p'$ —in other words, `false` is “input” into the rightmost `not` gate. Continuing the unification chain reaction, the rightmost dag for `true` is then forced to unify with the “output” node  $p''$ . Hence application of `notnot` to `true` yields an answer of the type of `true`.

When we replace `not` with  $\delta$ , and compose the coding  $\delta$  of the transition function of a TM with itself, the details of the unification become more complicated, but the high-level structure of this argument remains unchanged. As in the case of `Notnot`, the left hand side of the dag coding the type of  $\delta$  has considerable structure, while the right hand side is simply an external node (see Figure 5). Assume that  $\phi$  is the type of  $\delta$ ; we unify the dag  $\mathcal{C}_1$  (the so-called “TM circuitry”) with a dag coding a TM ID. A dag coding the next ID of the TM is then forced to unify with node  $ID'$ , and subsequent unification with the next copy  $\mathcal{C}_2$  of TM circuitry simulates another transition, unifying  $ID''$  with the following TM instantaneous description.

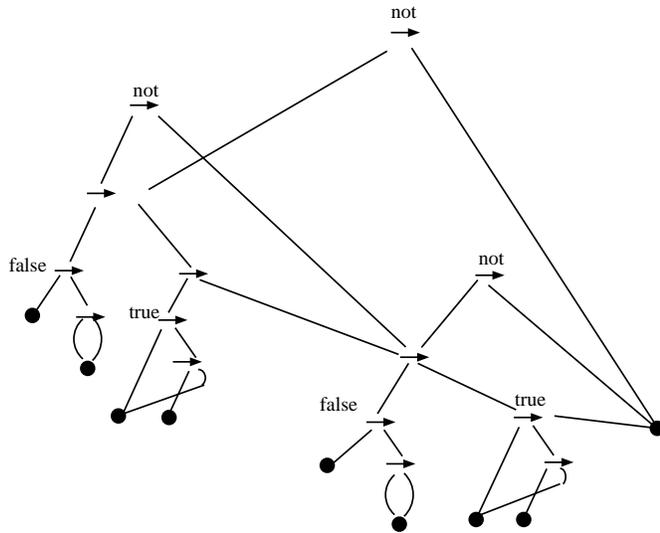

Figure 4: Graph representation of the type of Notnot

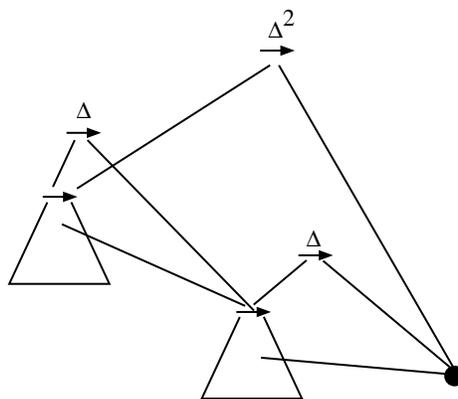

Figure 5: Graph representation of the composition of  $\delta$

The essential property allowing polymorphic functions to be so composed is that the right hand side of the dag encoding the type can be parameterized (i.e., instantiated by grafting of appropriate dags to the external nodes) to be identical to the left hand side. When the right hand side is simply a node (as in the case of the type of unary Boolean functions, and the type of  $\delta$  as well), this property is obvious. Observe that the type  $\phi^2$  of  $\delta \circ \delta$  then has the same property, and so it too can be composed with itself. In Section 5, we will formalize this general property in the type language of  $F_\omega$  to derive a nonelementary bound on type inference.

Given these intuitions about composing functions, the proof of the first part of the Proposition is straightforward: it follows from principles of first-order unification. We can, however, elaborate further on the second part.

Define  $\lambda$ -term  $\bar{k} \equiv \lambda s. \lambda z. s^k z$  and type  $\delta \in \Phi \equiv \Delta v_1:*. \Delta v_2:*. \dots \Delta v_r:*. \mathcal{L}(v_1, v_2, \dots, v_r) \rightarrow \mathcal{R}(v_1, v_2, \dots, v_r)$ , where  $\mathcal{L}(v_1, v_2, \dots, v_r)$  and  $\mathcal{R}(v_1, v_2, \dots, v_r)$  are *metanotation* representing quantifier-free (i.e., first-order) types over type variables  $v_1, v_2, \dots, v_r$ . Given these definitions, we type  $(\bar{k} \delta) ID$  so that  $\bar{k}$  has type

$$\lambda s: \Phi. \lambda z: \sigma. s[\pi_{1,1}] \dots [\pi_{1,r}] (s[\pi_{2,1}] \dots [\pi_{2,r}] \dots (s[\pi_{k,1}] \dots [\pi_{k,r}] z) \dots)$$

where the  $\pi_{i,j}$  are quantifier-free parameterizations of  $\Phi$  such that if  $s[\pi_{i,1}] \dots [\pi_{i,r}]$  has type  $\alpha \rightarrow \beta$ , then  $\alpha$  unifies with  $\sigma^{k-i}$ , and  $\beta$  is equal to  $\sigma^{k-i+1}$  (up to renaming of type variables). We can then assign to  $z$  a type *unifying with*  $\sigma \equiv \sigma^0$ , and assign term  $s^k z$  the type  $\sigma^k$ . ■

The typing of  $\bar{k} \delta$  in the above Proposition uses an essential feature of  $F_2$ : observe that the type of  $\bar{k}$  is not outermost-quantified, since the type of  $s$  is the (polymorphic) type of  $\delta$ , containing quantifiers.

**Corollary 3.3** *Let  $\bar{k}$  denote the Church numeral for  $\lambda s. \lambda z. s^k z$ , and let*

$$E \equiv (\lambda f. \bar{2}(\bar{2} \dots (\bar{2} f) \dots)) \delta ID_0,$$

where there are  $m$  occurrences of  $\bar{2}$ , and  $ID_0$  codes an initial ID of  $M$ . Then  $E$  has the same normal form and rank 2 type as  $(\bar{2}^m \delta) ID_0$ .

**Proof.** We write  $\Delta \vec{v}_t:*$  (respectively,  $\Delta \vec{v}_t:*$ ) to denote abstraction over a sequence  $v_1, \dots, v_t$  of type variables, and  $[\vec{\pi}]$  to denote a sequence of parameterizations. We then write the type pictured in Figure 5 as  $\Delta \vec{v}_t v_{\text{out}}:*. \mathcal{L}(\vec{v}_t v_{\text{out}}) \rightarrow v_{\text{out}}$ , where  $\mathcal{L}$  is a *type functional* mapping  $t+1$  types to a type.<sup>12</sup> Here, as in Proposition 3.2,  $\mathcal{L}$  is a *metanotation*, since it clearly is not part of the syntax of the type language of  $F_2$ ; we see in Section 5 how constructs similar to  $\mathcal{L}$  can be formalized in  $F_\omega$ . Using this notation, the rightmost  $\bar{2}$  in  $E$  can be given the type

$$\begin{aligned} \tau_1 \equiv & (\Delta \vec{v}_t v_{\text{out}}:*. \mathcal{L}(\vec{v}_t v_{\text{out}}) \rightarrow v_{\text{out}}) \rightarrow \\ & \Delta \vec{v}'_t v'_{\text{out}}:*. \mathcal{L}(\vec{v}'_t v'_{\text{out}}) \rightarrow v'_{\text{out}}, \end{aligned}$$

---

<sup>12</sup>Observe the informal use of concatenation of type variables, e.g.,  $\Delta \vec{v}_t v_{\text{out}}:*$  denotes the type  $\Delta v_1:*. \Delta v_2:*. \dots \Delta v_t:*. \Delta v_{\text{out}}:*$ .

that is,

$$\begin{aligned}
\lambda \mathbf{g}: \Delta \vec{v}_t v_{\text{out}}: * . \mathcal{L}(\vec{v}_t v_{\text{out}}) &\rightarrow v_{\text{out}}. \\
\Lambda \vec{v}_t: * . \Lambda \vec{v}'_t: * . \Lambda v'_{\text{out}}: * . \\
\lambda \mathbf{y}: \mathcal{L}(\vec{v}_t \mathcal{L}(\vec{v}'_t v'_{\text{out}})) & \\
\mathbf{g}[\vec{v}'_t][v'_{\text{out}}] & \\
(\mathbf{g}[\vec{v}_t][\mathcal{L}(\vec{v}'_t v'_{\text{out}})] \mathbf{y}) &
\end{aligned}$$

Iterating this construction, we can type the second rightmost  $\bar{2}$  as

$$\begin{aligned}
\lambda \mathbf{g}: \Delta \vec{v}_t \vec{v}'_t v'_{\text{out}}: * . \mathcal{L}(\vec{v}_t \mathcal{L}(\vec{v}'_t v'_{\text{out}})) &\rightarrow v'_{\text{out}}. \\
\Lambda \vec{v}_t: * . \Lambda \vec{v}'_t: * . \Lambda \vec{v}''_t: * . \Lambda \vec{v}'''_t: * . \Lambda v'''_{\text{out}}: * . \\
\lambda \mathbf{y}: \mathcal{L}(\vec{v}_t \mathcal{L}(\vec{v}'_t \mathcal{L}(\vec{v}''_t \mathcal{L}(\vec{v}'''_t v'''_{\text{out}})))) & \\
\mathbf{g}[\vec{v}''_t][\vec{v}'''_t][v'''_{\text{out}}] & \\
(\mathbf{g}[\vec{v}_t][\vec{v}'_t][\mathcal{L}(\vec{v}''_t \mathcal{L}(\vec{v}'''_t v'''_{\text{out}}))] \mathbf{y}) &
\end{aligned}$$

with type

$$\begin{aligned}
\tau_2 \equiv (\Delta \vec{v}_t \vec{v}'_t v'_{\text{out}}: * . \mathcal{L}(\vec{v}_t \mathcal{L}(\vec{v}'_t v'_{\text{out}})) &\rightarrow v'_{\text{out}}) \rightarrow \\
\Delta \vec{v}_t \vec{v}'_t \vec{v}''_t \vec{v}'''_t v'''_{\text{out}}: * . & \\
\mathcal{L}(\vec{v}_t \mathcal{L}(\vec{v}'_t \mathcal{L}(\vec{v}''_t \mathcal{L}(\vec{v}'''_t v'''_{\text{out}})))) &\rightarrow v'''_{\text{out}}
\end{aligned}$$

We continue the iteration to type each occurrence of  $\bar{2}$ , deriving a typing  $\tau$  of  $\bar{2}(\bar{2}(\dots(\bar{2}f)\dots))$ , and hence a typing of  $(\lambda f. \bar{2}(\bar{2}(\dots(\bar{2}f))))\delta$ . We then type  $E$  by first-order unifying the type of  $ID_0$  with the left hand side of  $\tau$ . This unification is indeed possible, using an induction on  $m$ ; we know the type of  $ID_0$  unifies with  $\phi \equiv \Delta \vec{v}_t v_{\text{out}}: * . \mathcal{L}(\vec{v}_t v_{\text{out}}) \rightarrow v_{\text{out}}$  as a basis, and the left hand side of  $\tau$  extends  $\phi$  at the output variable. We then use the inductive step to follow through the “chain reaction” of subsequent unifications with separate copies of TM circuitry. Since  $E$  reduces to  $(\bar{2}^m \delta)ID_0$ , the result follows from the so-called *subject reduction theorem* (see, e.g., [HS65]), the  $\lambda$ -calculus interpretation of cut elimination: namely, if a term has a particular type, then any reduct of that term has the same type.  $\blacksquare$

We remark that the *rank 2 typing* refers to the fact that rank 2 is necessary for the type derivation, although the actual type of  $E$  is rank 1.

**Theorem 3.4** *Recognizing the typable Core ML terms typable in  $F_2$  is  $\text{DTIME}[2^{n^t}]$ -hard for any integer  $t \geq 1$  under logspace reduction.*

**Proof.** For a description of Core ML—essentially, the first-order typed  $\lambda$ -calculus with a polymorphic **let** such that **let**  $x = E$  **in**  $B$  is syntactic sugar for  $[E/x]B$ —see [HMT90, KMM91, Mai92a]. Assume that  $F = \{q_{p+1}, \dots, q_k\} \subset Q$  are the accepting states of  $M$ . We define a combinator

$$Eq \equiv \lambda x. \lambda y. K x (\lambda z. K (zx)(zy)) \in \Delta a: * . a \rightarrow a \rightarrow a$$

and consider the ML expression

$$\begin{aligned}
\Psi \equiv & \text{let } \delta_0 = \delta \text{ in} \\
& \text{let } \delta_1 = \lambda y. \delta_0(\delta_0 y) \text{ in} \\
& \text{let } \delta_2 = \lambda y. \delta_1(\delta_1 y) \text{ in} \\
& \dots \\
& \text{let } \delta_{n^t} = \lambda y. \delta_{n^t-1}(\delta_{n^t-1} y) \text{ in} \\
& \delta_{n^t} ID_0 (\lambda \text{state}. \lambda \ell. \lambda r. Eq I ((\text{state false} \dots \text{false true} \dots \text{true}) I K))
\end{aligned}$$

where the first  $p$  arguments of  $\text{state}$  are  $\text{false}$ , and the remaining  $k - p$  arguments are  $\text{true}$ . If TM  $M$  accepts its input, then  $R \equiv \text{state false} \dots \text{false true} \dots \text{true}$  reduces to  $\text{true}$ , so that  $R I K \triangleright I$ , and  $Eq I I$  can be typed. If TM  $M$  rejects its input, then  $R I K \triangleright K$ , and  $Eq I K$  cannot be typed, since the types of  $I$  and  $K$  are not first-order unifiable, and the type constraints of  $Eq$  force their type equality. ■

The construction in the above Theorem depends two basic components: a short coding of a long reduction sequence, and a gadget (based on first-order unification) to force a mistyping in the case of a rejecting computation. To derive a similar lower bound for  $F_2$ , we replace the coding of the reduction sequence by the construction of Corollary 3.3, and the mistyping gadget by one based on the strong normalization theorem for  $F_2$ .

**Theorem 3.5** *Recognizing the lambda terms typable in  $F_2$  is  $\text{DTIME}[2^{n^t}]$ -hard for any integer  $t \geq 1$  under logspace reduction.*

**Proof.** Again, assume that  $F = \{q_{p+1}, \dots, q_k\} \subset Q$  are the accepting states of  $M$ . Consider

$$\begin{aligned}
A \equiv & \langle q, L, R \rangle = (\lambda f. \bar{2}(\bar{2} \dots (\bar{2} f) \dots)) \delta ID_0; \\
& q \text{ false } \dots \text{ false true } \dots \text{ true}
\end{aligned}$$

where  $\bar{2}$  occurs  $n^t$  times, the first  $p$  arguments of  $q$  are  $\text{false}$  and the remaining  $k - p$  arguments are  $\text{true}$ . If  $M$  accepts input  $x$  after exactly  $2^{n^t}$  steps, then  $A$   $\beta$ -reduces to  $\text{true}$ . By Lemma 3.2 and Corollary 3.3, the  $\lambda$ -expression  $A$  can be given type  $\Delta\alpha:*. \Delta\beta:*. \alpha \rightarrow \beta \rightarrow \alpha$ , so that  $\Psi_{M,x} \equiv (\lambda x. xx)(A (\lambda x. x) (\lambda y. yy))$  is typable in rank 3:

$$\begin{aligned}
& (\lambda \mathbf{x}: \Delta\tau:*. \tau \rightarrow \tau. \mathbf{x} [\Delta\tau:*. \tau \rightarrow \tau] \mathbf{x}) \\
& (A [\Delta\tau:*. \tau \rightarrow \tau][(\Delta\tau:*. \tau \rightarrow \tau) \rightarrow (\Delta\tau:*. \tau \rightarrow \tau)](\Lambda\tau:*. \lambda \mathbf{x}: \tau. \mathbf{x}) \\
& (\lambda \mathbf{y}: \Delta\tau:*. \tau \rightarrow \tau. \mathbf{y} [\Delta\tau:*. \tau \rightarrow \tau] \mathbf{y}))
\end{aligned}$$

If  $M$  rejects  $x$ , then  $A$   $\beta$ -reduces to  $\lambda x. \lambda y. y$ , and consequently  $\Psi_{M,x}$  reduces to  $(\lambda x. xx)(\lambda y. yy)$ . By Girard's strong normalization theorem [Gir72, GLT89],  $\Psi_{M,x}$  is not  $F_2$ -typable. It is easily seen that  $\Psi_{M,x}$  can be constructed in logarithmic space from  $M$  and  $x$ , since the transducer need only count how many copies of the term  $\bar{2}$  to output in the construction of  $A$ . ■

**Corollary 3.6** (*Fixed type inference*) *Let  $\tau$  be an arbitrary but fixed  $F_2$  type that is inhabited, so that some lambda term exists with type  $\tau$ . Then the problem of recognizing the lambda terms which can be given the  $F_2$  type  $\tau$  is also  $\text{DTIME}[2^{n^t}]$ -hard for any integer  $t \geq 1$  under logspace reduction.*

## 4 An overview of $F_3, F_4, \dots, F_\omega$

The  $F_2$  lower bound given above has two parts: (1) a simulation of the transition function of an arbitrary TM by a closed  $\lambda$ -term; and (2) a method for composing the transition function an exponential number of times. The analogous ML bound stops at exponential because of ML’s limited ability to (polymorphically) compose arbitrary functions. No such limit is apparent in  $F_2$  or its higher-order extensions, so a natural place to strengthen the  $F_2$  bound is to improve the function composition realized in (2) and thus “turn the ‘crank’ (of the transition function) faster.” Note that the “crank” of Example 3.1 is (without syntactic sugar) merely the  $\lambda$ -term

$$(\lambda x_0. (\lambda x_1. \dots (\lambda x_{t-1}. (\lambda x_t. x_t) (\lambda y. x_{t-1} (x_{t-1} y))) \dots (\lambda y. x_1 (x_1 y))) (\lambda y. x_0 (x_0 y))) \delta,$$

which has the same power as the term  $E$  in Corollary 3.3. Might there be more powerful typable reduction sequences in the systems  $F_k$ ?

We show this program can be carried out in  $F_\omega$  to derive a nonelementary lower bound. Related superexponential bounds can be proven for the  $F_k$  so that recognizing typable  $\lambda$ -terms of length  $n$  requires  $f_k(n)$  time, where  $f_k(n)$  is an “exponential” stack of 2s growing linearly with  $k$ , and  $n$  on top of the stack. Before describing these lower bounds in more detail, we provide a brief overview of the type systems  $F_3, F_4, \dots, F_\omega$ .

### 4.1 Kinds and abstraction over functions on types

In the first-order typed  $\lambda$ -calculus, the type language is made up of type variables, and a binary function  $\rightarrow$  mapping a pair of types to a type. In  $F_2$ , we add universal quantification, but only over type variables. The higher-order systems  $F_3, F_4, \dots, F_\omega$  are designed to allow abstraction and quantification as well over *functions* on types, with varying degrees of freedom.

We introduce the notion of *kinds* to categorize types, similar to our use of types to categorize terms. For instance, we use  $*$  (sometimes pronounced “prop,” as in *logical proposition*) to denote the types found in  $F_2$ . (Not coincidentally, these types all have the essential syntax of logical propositions.) We describe the functionality of the (curried) function-space constructor  $\rightarrow$  as  $\rightarrow \in * \Rightarrow * \Rightarrow *$ , where  $\Rightarrow$  is a version of  $\rightarrow$  at the *kind* level; the significance of this description is that, given two types  $\tau_1$  and  $\tau_2$  of kind  $*$ , the expression  $\rightarrow \tau_1 \tau_2$  (usually written as the infix  $\tau_1 \rightarrow \tau_2$ ) is also of kind  $*$ . Interpreted logically, this merely asserts that if  $\tau_1$  and  $\tau_2$  are logical propositions, so is  $\tau_1 \rightarrow \tau_2$ . Though  $\rightarrow$  is not an  $F_2$  *type*, we see clearly that it is a *type constructor*.

Following these intuitions, if we introduce  $\lambda$ -abstraction at the *type* level, imitating its existence at the expression level, we can describe other functions on types, and abstract over such functions. For example, given an arbitrary type  $A$ , the type  $\Delta P: *. (A \rightarrow P \rightarrow P) \rightarrow P \rightarrow P$  can be used to code the type of *lists* of elements of type  $A$ , where we code the list  $[x_1, x_2, \dots, x_k]$  as the term

$$\Delta P: *. \lambda c: A \rightarrow P \rightarrow P. \lambda n: P. c \ x_1 (c \ x_2 (\dots (c \ x_k \ n))).$$

Observe that with type information removed, this term is simply  $\lambda c. \lambda n. c \ x_1 (c \ x_2 (\dots (c \ x_k \ n)))$ , virtually identical to the familiar **cons**  $x_1$  (**cons**  $x_2$  ( $\dots$  (**cons**  $x_k$  **nil**))), except that we have abstracted over the constructors **cons** and **nil**.

By abstracting over the arbitrary type  $A$ , we might define

$$\mathbf{List} \equiv \lambda A:*. \Delta P:*. (A \rightarrow P \rightarrow P) \rightarrow P \rightarrow P$$

so that, for instance, we could write  $Id$  [ $\mathbf{List} \text{ lnt}$ ] to parameterize the identity function with the type of lists of integers.

In this case,  $\mathbf{List}$  becomes a higher-order type of  $kind * \Rightarrow *$  that, for example, maps  $\mathbf{lnt}$  (of kind  $*$ ) to  $\mathbf{List} \text{ lnt} \equiv \Delta P:*. (\mathbf{lnt} \rightarrow P \rightarrow P) \rightarrow P \rightarrow P$  (also of kind  $*$ ). To use such definitions, equivalents of  $\alpha$ -renaming and  $\beta$ -reduction must be introduced at the *type* level to effect substitution. Other examples of higher-order types and complex kinds occur in the encoding of intuitionistic logical connectives using minimal second order logic:

$$\begin{aligned} \mathit{not} &\equiv \lambda A:*. A \rightarrow \Delta P:*. P \\ \mathit{and} &\equiv \lambda A:*. \lambda B:*. \Delta P:*. (A \rightarrow B \rightarrow P) \rightarrow P \\ \mathit{or} &\equiv \lambda A:*. \lambda B:*. \Delta P:*. (A \rightarrow P) \rightarrow (B \rightarrow P) \rightarrow P \end{aligned}$$

In these examples,  $\mathit{not}$  has kind  $* \Rightarrow *$ , while  $\mathit{and}$  and  $\mathit{or}$  have kind  $* \Rightarrow * \Rightarrow *$ . As we remarked earlier, observe that the idea of higher-order types takes what we might have used as *metanotation* in  $F_2$  (giving names to complicated types we tired of writing over and over with minor changes, for instance the construction  $\mathcal{L}$  in Section 3.7), and embeds the notation formally in the typed  $\lambda$ -calculus under consideration, along with requisite substitution mechanisms at the type level.

The type systems  $F_k$  differ in the degree to which they allow this higher-order type abstraction. In  $F_2$ , no such  $\lambda$ -abstraction is allowed, and all types have kind  $*$ . In  $F_3$ ,  $\lambda$ -abstraction is allowed only over types of kind  $*$ , and in  $F_{k+1}$  abstraction is allowed only over types of kinds found in  $F_k$ . In  $F_\omega$ , there are no such restrictions. We can describe the kinds  $\mathcal{K}_k$  allowed in  $F_k$  by a grammar:

$$\begin{aligned} \mathcal{K}_2 &::= * \\ \mathcal{K}_{\ell+1} &::= \mathcal{K}_\ell \mid \mathcal{K}_\ell \Rightarrow \mathcal{K}_{\ell+1} \\ \mathcal{K}_\omega &::= * \mid \mathcal{K}_\omega \Rightarrow \mathcal{K}_\omega \end{aligned}$$

## 4.2 Syntax and inference rules for the systems $F_3, F_4, \dots, F_\omega$

The syntax and inference rules of  $F_3, F_4, \dots, F_\omega$  are a generalization of those found for  $F_2$  in Section 2.1. The systems differ only in their definition of kinds. Let  $\mathcal{K}$  denote a grammar of kinds as described above; we then define the syntax of types and expressions as:

$$\begin{aligned} \mathcal{T} &::= \alpha \mid \mathcal{T} \rightarrow \mathcal{T} \mid \Delta\alpha: \mathcal{K}. \mathcal{T} \mid \lambda\alpha: \mathcal{K}. \mathcal{T} \mid \mathcal{T} \mathcal{T} \\ \mathcal{E} &::= x \mid \lambda x: \mathcal{T}. \mathcal{E} \mid \mathcal{E} \mathcal{E} \mid \Lambda\alpha: \mathcal{K}. \mathcal{E} \mid \mathcal{E} [\mathcal{T}] \end{aligned}$$

We have the inference rules defining well formed contexts:

$$\begin{array}{l} (\mathit{Env}\langle \rangle) \quad \frac{}{\mathbf{wf}(\langle \rangle)} \\ (\mathit{Env}\text{-term}) \quad \frac{? \vdash \tau \in *}{\mathbf{wf}(? [x: \tau])} \\ (\mathit{Env}\text{-type}) \quad \frac{\mathbf{wf}(?)}{\mathbf{wf}(? [\alpha: K])} \quad \alpha \notin \mathbf{FV}(?) \end{array}$$

Next, we define the well-formedness of types:

$$\begin{array}{l}
(\text{Type-var}) \quad \frac{\text{wf}(?)}{? \vdash \alpha \in K} \quad ?(\alpha) = K \\
(\text{Wff} \rightarrow) \quad \frac{? \vdash \tau \in * \quad ? \vdash \tau' \in *}{? \vdash \tau \rightarrow \tau' \in *} \\
(\text{Wff} \Delta) \quad \frac{?[\alpha: K] \vdash \tau \in *}{? \vdash \Delta\alpha: K.\tau \in *} \\
(\Rightarrow \text{-int}) \quad \frac{?[\alpha: K] \vdash \tau \in K'}{? \vdash \lambda\alpha: K.\tau \in K \Rightarrow K'} \\
(\Rightarrow \text{-elim}) \quad \frac{? \vdash \tau \in K \Rightarrow K' \quad ? \vdash \tau' \in K}{? \vdash \tau\tau' \in K'}
\end{array}$$

The last rules define the well-typedness of expressions, in a syntax-directed fashion. Observe that the (constant) function-type constructor  $\rightarrow$  can only be applied to two terms of kind  $*$ . Notice also the introduction of rules defining the meaning of  $\lambda$  at the *type* level.

$$\begin{array}{l}
(\text{Var}) \quad \frac{? \vdash \tau \in *}{? \vdash x \in \tau} \quad ?(x) = \tau \\
(\rightarrow \text{-int}) \quad \frac{? \vdash \tau \in * \quad ?[x: \tau] \vdash e \in \tau'}{? \vdash \lambda x: \tau. e \in \tau \rightarrow \tau'} \\
(\rightarrow \text{-elim}) \quad \frac{? \vdash e \in \tau \rightarrow \tau' \quad ? \vdash e' \in \tau}{? \vdash ee' \in \tau'} \\
(\Delta \text{-int}) \quad \frac{?[\alpha: K] \vdash e \in \tau}{? \vdash \Lambda\alpha: K. e \in \Delta\alpha: K.\tau} \quad \alpha \notin \text{FV}(?) \\
(\Delta \text{-elim}) \quad \frac{? \vdash e \in \Delta\alpha: K.\tau' \quad ? \vdash \tau \in K}{? \vdash e[\tau] \in \tau'[\alpha/\tau]} \\
(\approx) \quad \frac{? \vdash e \in \tau' \quad \tau \approx \tau' \quad ? \vdash \tau \in *}{? \vdash e \in \tau}
\end{array}$$

In the last rule,  $\tau \approx \tau'$  means that the types are  $\beta\eta$ -convertible.

## 5 Type inference for $F_\omega$ is nonelementary

To derive a nonelementary bound, we show how to type the  $\lambda$ -term  $C \delta ID_0$ , where

$$C \equiv (\lambda f. \lambda x. f^2 x)(\lambda g_n. \lambda y_n. g_n^2 y_n)(\lambda g_{n-1}. \lambda y_{n-1}. g_{n-1}^2 y_{n-1}) \cdots (\lambda g_0. \lambda y_0. g_0^2 y_0),$$

and  $\delta$  and  $ID_0$  code the transition function and initial ID of a TM, as in Section 3. The method we describe for typing  $C$  makes very broad assumptions about the reductions caused by  $\delta$ , and thus provides a general technique for composing functions. Observe that

$$C \delta ID_0 \triangleright (\lambda y_1. \lambda y_0. y_1^{\Phi(n+2)} y_0) \delta ID_0 \triangleright \delta^{\Phi(n+2)} ID_0,$$

where the function  $\Phi$  is defined as  $\Phi(0) = 1$ ,  $\Phi(a+1) = 2^{\Phi(a)}$ .<sup>13</sup> The technical challenge is to type  $C$  so that  $y_1$  gets the type of  $\delta$ , and  $y_0$  the type of  $ID_0$ . The term  $C$  codes repeated exponentiation

<sup>13</sup>Recall from Section 2 that the term  $(\lambda s. \lambda z. s^m z) (\lambda s. \lambda z. s^n z)$  reduces to the normal form  $\lambda s. \lambda z. s^{n^m} z$ . Therefore, a  $\lambda$ -term consisting of a (left associating) sequence of  $k$  Church numerals for 2 will normalize to the Church numeral denoting a stack of  $n$  2s.

as in Example 3.1, *except* that the function  $\delta$  being composed does not have the same domain and range. To understand how to compose functions with different domains and ranges, we have to examine the type of  $\delta$  more closely; we abstract its structure as:

$$\begin{aligned} \delta &\in \Delta v_1:*. \Delta v_2:*. \cdots \Delta v_r:*. \\ &\quad \overline{\mathcal{L}}(v_1, v_2, \dots, v_r) \rightarrow \overline{\mathcal{R}}(v_1, v_2, \dots, v_r). \end{aligned}$$

**Proposition 5.1**  $\overline{\mathcal{L}}(v_1, v_2, \dots, v_r)$  is a substitution instance of  $\overline{\mathcal{R}}(w_1, w_2, \dots, w_r)$ .

**Proof.** They both encode TM IDs, and so are unifiable. The “circuitry” of the unification logic exists on the “ $\overline{\mathcal{L}}$ ” side, which induces structure on the “ $\overline{\mathcal{R}}$ ” side. ■

The construction that follows may in fact be used to type the iteration of *any* function  $\delta$ , provided that the above Proposition is satisfied.

We now represent the type of  $\delta$  by using higher-order type constructors. Divide the type variables  $V = \{v_1, \dots, v_r\}$  into disjoint sets  $V_I = \{v_1, \dots, v_p\}$  and  $V_O = \{v_{p+1}, \dots, v_{p+q=r}\}$ , where the *output variables*  $V_O$  appear in  $\overline{\mathcal{R}}(v_1, v_2, \dots, v_r)$ , and the *intermediate variables*  $V_I$  form the complement. For example, in Figure 3.7, the type of *not* has a single output variable (the rightmost node labelled *p true false*), while the other external nodes of the graph comprise the intermediate variables. We can then define an *ID-constructor make-ID* as a function on types:

$$\begin{aligned} \text{make-ID} &\equiv \lambda x_1:*. \lambda x_2:*. \cdots \lambda x_q:*. \\ &\quad \mathcal{R}(x_1, x_2, \dots, x_q) \in *^{q+1}, \end{aligned}$$

where we use the abbreviation  $*^1 \equiv *$ ,  $*^{a+1} \equiv * \Rightarrow *^a$ , and  $\mathcal{R}$  is  $\overline{\mathcal{R}}$  restricted to the output variables.

**Lemma 5.2** *There exist type functions  $?_i \in *^{r+1}$ ,  $1 \leq i \leq q$ , such that the type of  $\delta$  can be represented as:*

$$\begin{aligned} \delta &\in \Delta v_1:*. \Delta v_2:*. \cdots \Delta v_r:*. \\ &\quad (\text{make-ID } (?_1 v_1 v_2 \cdots v_r) (?_2 v_1 v_2 \cdots v_r) \cdots (?_q v_1 v_2 \cdots v_r)) \\ &\quad \rightarrow \text{make-ID } v_{p+1} v_{p+2} \cdots v_{p+q}. \end{aligned}$$

**Proof.** By first-order unification and Proposition 5.1. We remark that the functions  $?_i$  encode what we have called “TM circuitry.” In fact, for the coding of the TM we have given, the right hand side of the type of  $\delta$  consists of a single output variable, so  $q = 1$ , there is only one functional  $?_1$ , and  $\text{make-ID} \equiv \lambda x:*. x$ . We maintain this more general notation to treat composition of polymorphic functions with more complex types. ■

How is  $\delta$  composed *polymorphically*, namely the equivalent of ML’s `let  $\delta^2 = \lambda ID. \delta(\delta ID)$` ? In ML, the type of  $\delta^2$  is realized by first-order unification; we simulate this using the functions  $?_i$ .

**Proposition 5.3** *The  $\lambda$ -term  $\delta^2$  can be given the  $F_\omega$ -type*

$$\begin{aligned}
& \Delta v_1: * . \Delta v_2: * . \cdots \Delta v_p: * . \Delta v'_1: * . \Delta v'_2: * . \cdots \Delta v'_r: * . \\
& \text{(make-ID)} \\
& \quad (?_1 v_1 v_2 \cdots v_p (?_1 v'_1 \cdots v'_r) \cdots (?_q v'_1 \cdots v'_r)) \\
& \quad (?_2 v_1 v_2 \cdots v_p (?_1 v'_1 \cdots v'_r) \cdots (?_q v'_1 \cdots v'_r)) \\
& \quad \cdots \\
& \quad (?_q v_1 v_2 \cdots v_p (?_1 v'_1 \cdots v'_r) \cdots (?_q v'_1 \cdots v'_r)) \\
& \rightarrow \text{make-ID } v'_{p+1} v'_{p+2} \cdots v'_{p+q}.
\end{aligned}$$

Observe that the output variables  $v_{p+1}, \dots, v_{p+q}$  in the type of  $\delta$  have been instantiated so that  $v_{p+i} = ?_i v'_1 \cdots v'_r$ . The primed variables form a second *floor* of circuitry, while *make-ID* puts a *roof* on the type structures generated by the variables and the  $?_i$ . Repeated composition yields a giant directed acyclic graph, where the depth of the dag (i.e., the number of floors) is linearly proportional to the degree of composition.

The type constructors  $?_i$  and *make-ID* can therefore be used to define the types of  $\lambda$ -terms  $\lambda ID.\delta(\delta \cdots (\delta ID) \cdots)$  in normal form, where  $\delta$  is iterated some fixed number of times. However, in typing the  $\lambda$ -term  $C$  defined at the beginning of this section, we observe that  $C$  is not in normal form. In the next section, we use higher-order functionals to iterate the type constructors, so that the reduction of  $C$  to normal form at the value level proceeds in a well defined synchrony with reduction of the type constructors (and base types) to normal form at the type level.

## 5.1 Higher-order type data structures

We now show how  $\lambda$ -abstraction and application *at the type level* can be used to manufacture huge dags representing the  $t$ -fold composition of  $\delta$ . The existence of  $\lambda$  at the type level allows the construction of such “abstract” data structures.

The basic idea is the following: we construct a certain  $\lambda$ -term  $\mathcal{T}$  at the type level which in a precise sense *represents* the type of the  $j$ -fold composition of  $\delta$ , where the kind  $\kappa$  of  $\mathcal{T}$  does not depend on  $j$ . We will then define a function  $\text{map}: \kappa \Rightarrow \kappa$  such that  $\text{map } \mathcal{T}$  represents the type of the  $(j+1)$ -fold composition of  $\delta$ . *Because the domain and range (both kinds) of map are identical, we can at the type level engage in “conventional” function composition tricks that would not work at the expression level: the kind of map is identical to the kind of map  $\circ$  map.* On the other hand, considerable technology was developed earlier for composing particular functions at the expression level (e.g.,  $\delta$ ) that do not have identical domain and range. Notice that when we compose a function with identical domain and range, we may define, for instance,

$$\begin{aligned}
\overline{2}_0 & \equiv \lambda \sigma: \kappa \Rightarrow \kappa . \lambda \tau: \kappa . \sigma^2 \tau \\
& \in (\kappa \Rightarrow \kappa) \Rightarrow \kappa \Rightarrow \kappa \\
\overline{2}_1 & \equiv \lambda \sigma: (\kappa \Rightarrow \kappa) \Rightarrow \kappa \Rightarrow \kappa . \lambda \tau: \kappa \Rightarrow \kappa . \sigma^2 \tau \\
& \in ((\kappa \Rightarrow \kappa) \Rightarrow \kappa \Rightarrow \kappa) \Rightarrow \\
& \quad (\kappa \Rightarrow \kappa) \Rightarrow \kappa \Rightarrow \kappa
\end{aligned}$$

and write

$$\bar{2}_1 \bar{2}_0 \text{map} \triangleright \lambda \mathcal{T} : \kappa . \text{map}(\text{map}(\text{map}(\text{map } \mathcal{T}))).$$

The coding of the type  $\text{map}$  is not pretty, but its use is quite elegant. The fundamental data structure manipulated by  $\text{map}$  is called a *pair*. A pair has two parts: a *prototype*, and a *variable list*.

A *prototype* is a  $\lambda$ -term of the form

$$\lambda x_1 : * . \lambda x_2 : * . \dots \lambda x_q : * . \lambda \Phi' : *^{q+pt+1} . \Phi' \phi_1 \phi_2 \dots \phi_q d_1 \dots d_{pt}.$$

The  $d \equiv d_i$  are just “dummy” type variables to “pad” the kind, and the  $\phi_i$  are types involving some set  $v_1, \dots, v_{pt}$  of type variables,  $x_1, \dots, x_q$ , and  $\rightarrow$ , so each  $\phi_i$  is of kind  $*$ . We imagine the  $\phi_i$  to be the dag “under construction,” so that *make-ID*  $\phi_1 \dots \phi_q$  would form a suitable  $\mathcal{L}$ , given type variables for the  $x_i$ .

A *variable list* is a  $\lambda$ -term of the form

$$\lambda x_1 : * . \lambda x_2 : * . \dots \lambda x_q : * . \lambda \Phi' : *^{q+pt+1} . \Phi' f_1 f_2 \dots f_q v_1 \dots v_{pt},$$

where the  $f_i$  are the output variables (i.e., external nodes) of the dag ultimately to be constructed, and the  $v_i$  are a list of type variables to be used during the construction. The  $\lambda x_i$ -bindings are padding, since they make the kind of a prototype identical to the kind of a variable list.

A *pair* is a  $\lambda$ -term of the form

$$\begin{aligned} \lambda \Pi : \kappa' \Rightarrow \kappa' \Rightarrow \kappa' . \Pi P V \\ \in (\kappa' \Rightarrow \kappa' \Rightarrow \kappa') \Rightarrow \kappa', \end{aligned}$$

where  $P$  is a prototype and  $V$  is a variable list (both of kind  $\kappa'$ ). Because of the kind identity, **fst** and **snd** are definable on pairs:

$$\begin{aligned} \mathbf{fst} &\equiv \lambda \text{pair} : (\kappa' \Rightarrow \kappa' \Rightarrow \kappa') \Rightarrow \kappa' . \text{pair} (\lambda P : \kappa' . \lambda V : \kappa' . P) \\ \mathbf{snd} &\equiv \lambda \text{pair} : (\kappa' \Rightarrow \kappa' \Rightarrow \kappa') \Rightarrow \kappa' . \text{pair} (\lambda P : \kappa' . \lambda V : \kappa' . V) \end{aligned}$$

Given a prototype or variable list applied to types  $\tau_1, \dots, \tau_q$  of kind  $*$ , the result is a tuple of kind  $*^{q+pt+1} \Rightarrow *$ , and we may then code terms **project** $_{q+pt,j}$ , similar to the definitions of **fst** and **snd**, which project the  $j$ th type from the tuple. For a variable list  $V$ , we write  $V_j$  for **project** $_{q+pt,j}(V d_1 d_2 \dots d_q)$ .

The  $\lambda$ -term  $\text{map}$  maps pairs to pairs, where the new pair is one “composition step” closer to the ultimate  $t$ -fold composition, as represented by the prototype. The definition of  $\text{map}$  involves straightforward list processing on pairs, where the type variables in the variable list used as *intermediate variables* in the sense defined earlier are repeatedly *shifted cyclically* and retrieved as the “floors” are built; each floor represents the type of another iteration of  $\delta$ .

To facilitate the description of type functionals, we use an ML-like `let` syntax, where `let  $x = E$  in  $B$`  is syntactic sugar for  $(\lambda x.B)E$ . No ML-style “kind polymorphism” exists in this programming style: the type language is entirely monomorphic.

$$\begin{aligned}
\text{map} &= \lambda \text{pair}: (\kappa' \Rightarrow \kappa' \Rightarrow \kappa') \Rightarrow \kappa'. \\
&\quad \text{let } P = \text{fst } \text{pair} \text{ in} \\
&\quad \quad \text{let } V = \text{snd } \text{pair} \text{ in} \\
&\quad \quad \quad \text{let } P' = \lambda x_1:*. \dots \lambda x_q:*. \\
&\quad \quad \quad \quad \text{let } \text{graft} = \lambda?:*^{r+1}.? \ x_1 \ x_2 \ \dots \ x_q \ V_{q+1} \ V_{q+2} \ \dots \ V_{q+p} \ \text{in} \\
&\quad \quad \quad \quad \quad P \ (\text{graft } ?_1) \ (\text{graft } ?_2) \ \dots \ (\text{graft } ?_q) \\
&\quad \quad \quad \text{in} \\
&\quad \quad \text{let } V' = \lambda x_1:*. \dots \lambda x_q:*. \lambda \Phi':*^{q+pt+1} \rightarrow *. \\
&\quad \quad \quad \quad \Phi' \ V_1 \ \dots \ V_q \ V_{q+p+1} \ V_{q+p+2} \ \dots \ V_{q+pt} \ V_{q+1} \ V_{q+2} \ \dots \ V_{q+p} \ \text{in} \\
&\quad \quad \quad \lambda \Pi': \kappa' \Rightarrow \kappa' \Rightarrow \kappa'. \Pi' \ P' \ V'
\end{aligned}$$

The higher-order type functional `map` decomposes the pair into its prototype  $P$  and variable list  $V$ . It builds dags  $?_i \ x_1 \ x_2 \ \dots \ x_q \ V_{q+1} \ V_{q+2} \ \dots \ V_{q+p}$  out of  $\lambda$ -abstracted type variables  $x_j$ , which mark external nodes in the dag where subsequent grafting will take place, and type variables  $V_{q+j}$  extracted from the variable list. Applying prototype  $P$  to the constructed dags grafts the dags onto the external nodes of the dags  $\phi_j$  stored in the prototype, building the new “floor” of constructed circuitry. The type variables  $v_j$  in variable list  $V$  are cyclically shifted in assembly-line fashion, so that applying `map` again to the just-constructed pair will select a different set of type variables to build the next “floor” of circuitry. The variables  $f_j$  in the variable list are *not* rotated: they remain fixed, to be substituted as the final output variables.

To convert a prototype into a first-order type of the iterated polymorphic composition of  $\delta$ , we substitute the “final” type variables  $f_j$  from the variable list (which were never cyclically shifted) into the prototype, and `make-ID` is applied to the dags  $\phi_j$  that have tediously been constructed:

$$\begin{aligned}
\mathcal{I} &\equiv \lambda \text{pair}: (\kappa' \Rightarrow \kappa' \Rightarrow \kappa') \Rightarrow \kappa'. \\
&\quad \text{let } P = \text{fst } \text{pair} \text{ in} \\
&\quad \quad \text{let } V = \text{snd } \text{pair} \text{ in} \\
&\quad \quad \quad \text{let } T = P \ V_1 \ V_2 \ \dots \ V_q \ \text{in} \\
&\quad \quad \quad \quad \text{make-ID} \ (\text{project}_{q+pt,1} T) \ (\text{project}_{q+pt,2} T) \ (\text{project}_{q+pt,q} T)
\end{aligned}$$

The relationship between these functionals and the type of iterative compositions of  $\delta$  is given by the following lemma:

**Lemma 5.4** *The  $\lambda$ -term  $\lambda ID.\delta(\delta \cdots (\delta ID))$ , where there are  $t$  instances of  $\delta$ , can be given type*

$$\begin{aligned}
& \Lambda d:*. \Lambda v_1:*. \Lambda v_2:*. \cdots \Lambda v_{q+pt}:*. \\
& \text{let } P = \lambda x_1:*. \cdots \lambda x_q:*. \lambda \Phi':*^{q+pt+1} \rightarrow *. \\
& \quad \Phi' x_1 \cdots x_q d \cdots d \text{ in} \\
& \text{let } V = \lambda x_1:*. \cdots \lambda x_q:*. \lambda \Phi':*^{q+pt+1} \rightarrow *. \\
& \quad \Phi' v_1 \cdots v_q v_{q+1} \cdots v_{q+pt} \text{ in} \\
& \text{let } \text{pair}_0 = \lambda \Pi: \kappa' \Rightarrow \kappa' \Rightarrow \kappa'. \Pi P V \text{ in} \\
& \quad \mathcal{I}(\text{map}(\text{map} \cdots (\text{map } \text{pair}_0) \cdots)) \rightarrow \mathcal{I}(\text{pair}_0)
\end{aligned}$$

where there are  $t$  instances of  $\text{map}$ .

As an example of the use of this Lemma, when  $t = 2$ , we get (without quantifiers) the type described in Proposition 5.3.

## 5.2 Composing $\text{map}$

Now comes the elegant and truly fun part: we use the “crank”

$$C \equiv (\lambda f.\lambda x.f^2x)(\lambda g_n.\lambda y_n.g_n^2y_n)(\lambda g_{n-1}.\lambda y_{n-1}.g_{n-1}^2y_{n-1}) \cdots (\lambda g_0.\lambda y_0.g_0^2y_0),$$

(at the *expression* level) to compose  $\text{map } \Phi(n+2)$  times, where  $\Phi(0) = 1$ ,  $\Phi(a+1) = 2^{\Phi(a)}$ . The dag gets constructed at a “speed” controlled by the reduction sequence of  $C$  to normal form. Let  $\kappa \equiv \kappa_0 \equiv (\kappa' \Rightarrow \kappa' \Rightarrow \kappa') \Rightarrow \kappa'$  be the kind of a pair, so that  $\text{map} \in \kappa_0 \Rightarrow \kappa_0$ , and  $\mathcal{I} \in \kappa_0 \Rightarrow *$ ; we define  $\kappa_{j+1} \equiv \kappa_j \Rightarrow \kappa_j$ , and let  $\alpha_j$  be a type variable of kind  $\kappa_{j+2}$ . Suppressing kinds temporarily to increase readability, we recursively define a set of types used to type  $C$ :

$$\begin{aligned}
\mathcal{G}_0\{\alpha_0\} & \equiv \Delta \text{map}.(\Delta \tau.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau) \rightarrow \\
& \quad (\Delta \tau.\mathcal{I}(\alpha_0 \text{map } \tau) \rightarrow \mathcal{I}\tau) \\
\mathcal{G}_1\{\alpha_1\} & \equiv \Delta \alpha_0.\mathcal{G}_0\{\alpha_0\} \rightarrow \mathcal{G}_0\{\alpha_1 \alpha_0\} \\
& \equiv \Delta \alpha_0.\mathcal{G}_0\{\alpha_0\} \rightarrow \\
& \quad \Delta \text{map}. \\
& \quad (\Delta \tau.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau) \rightarrow \\
& \quad (\Delta \tau.\mathcal{I}(\alpha_1 \alpha_0 \text{map } \tau) \rightarrow \mathcal{I}\tau) \\
\mathcal{G}_{k+1}\{\alpha_{k+1}\} & \equiv \Delta \alpha_k.\mathcal{G}_k\{\alpha_k\} \rightarrow \mathcal{G}_k\{\alpha_{k+1} \alpha_k\}
\end{aligned}$$

We may intuitively think of the  $\alpha_j$ ,  $j \geq 0$ , as the types of higher-order Church numerals, and  $\mathcal{G}_0\{\alpha_0\}$  as the type of an “ $\alpha_0$ -composer” which, given the transition function  $\delta$  of type  $\Delta \tau.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau$  as input, returns the  $\alpha_0$ -fold composition of  $\delta$  with itself. Accordingly,  $\mathcal{G}_1\{\alpha_1\}$  is the type of an “ $\alpha_1$ -composer composer” which, given an  $\alpha_0$ -composer, returns an  $\alpha_1 \alpha_0$ -composer. Recall that the normal form of  $\alpha_1 \alpha_0$  corresponds to *exponentiation* of the respective Church numerals, in the style of the introductory example of Section 2. In general,  $\mathcal{G}_{k+1}\{\alpha_{k+1}\}$  is the type of a function taking a higher-order composition function of type  $\mathcal{G}_k\{\alpha_k\}$ , and returning a more powerful iterator of type  $\mathcal{G}_k\{\alpha_{k+1} \alpha_k\}$ .

**Lemma 5.5** For each  $0 \leq i \leq n$ ,  $G_i \equiv \lambda g_i. \lambda y_i. g_i^2 y_i$  can be typed as  $\mathcal{G}_i\{\bar{2}_i\}$ , where

$$\bar{2}_i \equiv \lambda \sigma: \kappa_i \Rightarrow \kappa_i. \lambda \tau: \kappa_i. \sigma(\sigma \tau)$$

is a type having the same kind as  $\alpha_i$ , namely  $\kappa_{i+2} \equiv (\kappa_i \Rightarrow \kappa_i) \Rightarrow \kappa_i \Rightarrow \kappa_i$ .

**Proof.** For  $G_0 \equiv \lambda g_0. \lambda y_0. g_0^2 y_0$ , we have the construction

$$\begin{aligned} \mathbf{G}_0 &\equiv \Lambda \text{map}: \kappa_0 \Rightarrow \kappa_0. \\ &\lambda \mathbf{g}_0: \Delta \tau: \kappa_0. \mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I} \tau. \\ &\Lambda \tau: \kappa_0. \\ &\lambda \mathbf{y}_0: \mathcal{I}(\text{map}(\text{map } \tau)) \equiv \mathcal{I}(\bar{2}_0 \text{ map } \tau). \\ &\mathbf{g}_0 [\tau] (\mathbf{g}_0 [\text{map } \tau] \mathbf{y}_0) \end{aligned}$$

and for  $G_{i+1} \equiv \lambda g_{i+1}. \lambda y_{i+1}. g_{i+1}^2 y_{i+1}$ ,  $i \geq 0$ , we have the construction

$$\begin{aligned} \mathbf{G}_{i+1} &\equiv \Lambda \alpha_i: \kappa_{i+2}. \\ &\lambda \mathbf{g}_{i+1}: \mathcal{G}_i\{\alpha_i\} \equiv \Delta \alpha_{i-1}: \kappa_{i+1}. \mathcal{G}_{i-1}\{\alpha_{i-1}\} \rightarrow \mathcal{G}_{i-1}\{\alpha_i \alpha_{i-1}\}. \\ &\Lambda \alpha_{i-1}: \kappa_{i+1}. \\ &\lambda \mathbf{y}_{i+1}: \mathcal{G}_{i-1}\{\alpha_{i-1}\}. \\ &\mathbf{g}_{i+1} [\alpha_i \alpha_{i-1}] (\mathbf{g}_{i+1} [\alpha_{i-1}] \mathbf{y}_{i+1}) \end{aligned}$$

In this term, notice that

$$\begin{aligned} \mathbf{g}_{i+1} [\alpha_{i-1}] &\in \mathcal{G}_{i-1}\{\alpha_{i-1}\} \rightarrow \mathcal{G}_{i-1}\{\alpha_i \alpha_{i-1}\} \\ \mathbf{g}_{i+1} [\alpha_i \alpha_{i-1}] &\in \mathcal{G}_{i-1}\{\alpha_i \alpha_{i-1}\} \rightarrow \mathcal{G}_{i-1}\{\alpha_i(\alpha_i \alpha_{i-1})\} \end{aligned}$$

■

**Lemma 5.6** In the term  $C$ ,

$$F \equiv \lambda f. \lambda x. f^2 x \in \mathcal{G}_n\{\bar{2}_n\} \rightarrow \mathcal{G}_{n-1}\{\bar{2}_{n-1}\} \rightarrow \mathcal{G}_{n-1}\{\bar{2}_{n+1} \bar{2}_n \bar{2}_{n-1}\}.$$

**Proof.** We have the construction

$$\begin{aligned} \mathbf{F} &\equiv \lambda \mathbf{f}: \mathcal{G}_n\{\bar{2}_n\}. \\ &\lambda \mathbf{x}: \mathcal{G}_{n-1}\{\bar{2}_{n-1}\}. \\ &\mathbf{f} [\bar{2}_n \bar{2}_{n-1}] (\mathbf{f} [\bar{2}_{n-1}] \mathbf{x}) \end{aligned}$$

Recall  $\mathcal{G}_k\{\bar{2}_k\} \equiv \Delta \alpha_{k-1}: \kappa_{k+1}. \mathcal{G}_{k-1}\{\alpha_{k-1}\} \rightarrow \mathcal{G}_{k-1}\{\bar{2}_k \alpha_{k-1}\}$ ; with the given parameterizations, the subterms are typed as:

$$\begin{aligned} \mathbf{f} [\bar{2}_{n-1}] &\in \mathcal{G}_{n-1}\{\bar{2}_{n-1}\} \rightarrow \mathcal{G}_{n-1}\{\bar{2}_n \bar{2}_{n-1}\} \\ \mathbf{f} [\bar{2}_n \bar{2}_{n-1}] &\in \mathcal{G}_{n-1}\{\bar{2}_n \bar{2}_{n-1}\} \rightarrow \mathcal{G}_{n-1}\{\bar{2}_n(\bar{2}_n \bar{2}_{n-1})\} \end{aligned}$$

However, observe that by  $\beta$ -reduction at the type level,  $\bar{2}_n(\bar{2}_n \bar{2}_{n-1})$  and  $\bar{2}_{n+1} \bar{2}_n \bar{2}_{n-1}$  are equivalent.

■

**Theorem 5.7** *Recall the definitions of  $\mathbf{F}$  and  $\mathbf{G}_j$  from Lemmas 5.5 and 5.6. Then the term  $C$  (the “crank”) has typing*

$$\mathbf{C} \equiv \mathbf{F}\mathbf{G}_n\mathbf{G}_{n-1}[\bar{2}_{n-2}]\mathbf{G}_{n-2}[\bar{2}_{n-3}]\cdots\mathbf{G}_1[\bar{2}_0]\mathbf{G}_0$$

so that

$$\begin{aligned} \mathbf{C} &\in \mathcal{G}_0\{\bar{2}_{n+1}\bar{2}_n\cdots\bar{2}_0\} \\ &\equiv \Delta\text{map}:\kappa_0 \Rightarrow \kappa_0.(\Delta\tau:\kappa_0.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau) \rightarrow \\ &\quad (\Delta\tau:\kappa_0.\mathcal{I}((\bar{2}_{n+1}\bar{2}_n\cdots\bar{2}_0)\text{map } \tau) \rightarrow \mathcal{I}\tau) \\ &\triangleright \Delta\text{map}:\kappa_0 \Rightarrow \kappa_0.(\Delta\tau:\kappa_0.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau) \rightarrow \\ &\quad (\Delta\tau:\kappa_0.\mathcal{I}(\text{map}^{\Phi(n+2)} \tau) \rightarrow \mathcal{I}\tau) \end{aligned}$$

**Proof.** From Lemmas 5.5 and 5.6, we know that

$$\mathbf{F}\mathbf{G}_n\mathbf{G}_{n-1} \in \mathcal{G}_{n-1}\{\bar{2}_{n+1}\bar{2}_n\bar{2}_{n-1}\} \equiv \Delta\alpha_{n-2}:\kappa_n.\mathcal{G}_{n-2}\{\alpha_{n-2}\} \rightarrow \mathcal{G}_{n-2}\{\bar{2}_{n+1}\bar{2}_n\bar{2}_{n-1}\alpha_{n-2}\}.$$

By parameterizing this term with type  $\bar{2}_{n-2}$ , we derive a term of type

$$\mathcal{G}_{n-2}\{\bar{2}_{n-2}\} \rightarrow \mathcal{G}_{n-2}\{\bar{2}_{n+1}\bar{2}_n\bar{2}_{n-1}\bar{2}_{n-2}\}.$$

However, by Lemma 5.5, we know  $\mathbf{G}_{n-2} \in \mathcal{G}_{n-2}\{\bar{2}_{n-2}\}$ , so that

$$\begin{aligned} \mathbf{F}\mathbf{G}_n\mathbf{G}_{n-1}[\bar{2}_{n-2}]\mathbf{G}_{n-2} &\in \mathcal{G}_{n-2}\{\bar{2}_{n+1}\bar{2}_n\bar{2}_{n-1}\bar{2}_{n-2}\} \\ &\equiv \Delta\alpha_{n-3}:\kappa_{n-1}.\mathcal{G}_{n-3}\{\alpha_{n-3}\} \rightarrow \mathcal{G}_{n-3}\{\bar{2}_{n+1}\bar{2}_n\bar{2}_{n-1}\bar{2}_{n-2}\alpha_{n-3}\}. \end{aligned}$$

Formally, the proof consists of an induction on  $n$ ; informally, we continue to “unwind” the above construction. Each type parameterization  $\bar{2}_j$ , followed by application to  $\mathbf{G}_j$ , augments the exponential stack contained in the type with another  $\bar{2}$ . The reduction of the stack of  $\bar{2}$ s to normal form (at the type level) results in a nonelementary Church numeral applying  $\text{map}$  to a  $(\Delta\text{-bound})$  pair  $\tau$ .  $\blacksquare$

**Theorem 5.8** *Recognizing the lambda terms of length  $n$  typable in  $F_\omega$  is  $\text{DTIME}[\Phi(n^t)]$ -hard for any integer  $t \geq 1$  under logspace reduction, where*

$$\begin{aligned} \Phi(0) &= 1, \\ \Phi(a+1) &= 2^{\Phi(a)}. \end{aligned}$$

**Proof.** Again, we simulate the computation of a TM  $M$  accepting or rejecting its input  $x$  in  $\Phi(|x|^k)$  steps by a  $\lambda$ -term  $\Psi_{M,x}$ , where  $M$  accepts  $x$  if and only if  $\Psi_{M,x}$  is typable.

Using the typing of  $C$  in Theorem 5.7, we type  $\widehat{M} \equiv C \delta ID_0$  as:

$$\begin{aligned} \widehat{M} &\equiv (\Lambda d:*. \Lambda v_1:*. \cdots \Lambda v_{q+pt}:*. \mathbf{C}[\text{map}]\delta[\text{pair}_0]) \\ &\quad [\mu_d][\mu_1] \cdots [\mu_{q+pt}] (ID_0[\pi]) \end{aligned}$$

Observe that we take the type of the “crank” and parameterize it with the definition of  $\text{map}$ ; since  $\delta \in (\Delta\tau.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau)$ , we know  $\mathbf{C}[\text{map}]\delta \in \Delta\tau:\kappa_0.\mathcal{I}((\bar{2}_{n+1}\bar{2}_n\cdots\bar{2}_0)\text{map } \tau) \rightarrow \mathcal{I}\tau$ . Next,

parameterize this term over the *initial pair*  $pair_0$  defined in Lemma 5.4, and abstract over all the variables  $v_j$  appearing in the pair. The term thus constructed is the  $\Phi(t+2)$ -fold unwinding of the transition function, and its outermost-quantified first order type codes the reductions on an arbitrary ID as a directed acyclic graph.

To apply this term to an initial ID, we need to instantiate the quantified variables  $v_j$  so that the left hand side of the type is identical to a typing of the initial ID. The parameterization of each  $v_j$  by a type  $\mu_j$ , and the complementary parameterization  $\pi$  of the initial ID, simulates the unification process of the ML type inference algorithm. The instantiations are huge: the substitutions for intermediate variables on the “top floor” of the type will have nonelementary size. These instantiations must code the computation of the TM on the input.

The proof of the theorem now concludes exactly in the style of Theorem 3.5. By choosing the parameterizations of the output variables carefully, the term

$$A \equiv \langle q, L, R \rangle = \widehat{M}; \quad q \text{ false } \dots \text{ false true } \dots \text{ true},$$

where the instances of *true* and *false* are appropriate substitutions of Boolean terms for the accepting and rejecting states, will be given type  $\Delta\alpha:*\Delta\beta:*\alpha \rightarrow \beta \rightarrow \alpha$  if the TM accepts its input, and  $\Delta\alpha:*\Delta\beta:*\alpha \rightarrow \beta \rightarrow \beta$  if the TM rejects its input. Then  $\Psi_{M,x} \equiv (\lambda x.xx)(A (\lambda x.x)(\lambda y.yy))$  is typable if and only if the TM accepts its input. In the case of an accepting computation, the typing is straightforward; in the case of a rejecting computation, we appeal to the fact that all typable terms in  $F_\omega$  are strongly normalizing, and the term we have constructed is divergent.  $\blacksquare$

**Corollary 5.9** *Recognizing the lambda terms of length  $n$  typable in  $F_k$  is  $\text{DTIME}[f_{k-4}(n)]$ -hard under logspace reduction, where*

$$\begin{aligned} f_0(n) &= n, \\ f_{k+1}(n) &= 2^{f_k(n)}. \end{aligned}$$

**Proof.** The proof of the corollary is identical to that of the previous theorem, except that the restrictions on kinds imposed by  $F_k$  do not allow as powerful a “crank” as given in Theorem 5.7, because the type language does not have functionals of high enough order.

In particular, the “kinding” of prototypes and variable lists require the degree of higher-order abstraction found in system  $F_3$ ; this assertion can be verified by examining their respective kinds and the grammar of kinds found at the end of Section 4.1. As described in Section 5.1, pairs are representable in  $F_4$ , and *map* and  $\mathcal{I}$  are representable in  $F_5$ . The iterator  $\bar{2}_j$  is then representable in  $F_{j+6}$ . As a consequence, the typing of the term  $\mathbf{C}$  in Theorem 5.7 is realized in  $F_{n+6}$ . Observe that  $\mathcal{G}_j\{\bar{2}_j\}$  can then be represented in  $F_{j+5}$  by explicitly iterating the  $\bar{2}_j$ , i.e.,

$$\mathcal{G}_j\{\bar{2}_j\} \equiv \Delta\alpha_{j-1}:\kappa_{j+1}.\mathcal{G}_{j-1}\{\alpha_{j-1}\} \rightarrow \mathcal{G}_{j-1}\{\lambda\tau:\kappa_{j-2}.\alpha_{j-1}(\alpha_{j-1}\tau)\}$$

To achieve the simulation of an arbitrary TM for  $f_{k-4}(n)$  steps, we repeat the argument of Theorem 5.7, except that we replace the term  $F$  by  $N \equiv \lambda f.\lambda x.f^n x$ , which can be given type

$$\mathbf{N} \in \mathcal{G}_{k-5}\{\bar{2}_{k-5}\} \rightarrow \mathcal{G}_{k-6}\{\bar{2}_{k-6}\} \rightarrow \mathcal{G}_{k-6}\{\bar{n}_{k-4}\bar{2}_{k-5}\bar{2}_{k-6}\},$$

where  $\bar{n}$  is the analogous Church numeral for  $n$  at the type level. By once again carefully manipulating the typing, we can represent  $\bar{n}_{k-4}\bar{2}_{k-5}\bar{2}_{k-6}$  instead by a reduced form of the iteration, that is,

$\bar{2}_{k-5}(\bar{2}_{k-5}(\cdots(\bar{2}_{k-5}\bar{2}_{k-6})\cdots))$ , where  $\bar{2}_{k-5}$  is iterated  $n$  times. The typed “crank” that iterates the computation is then

$$\mathbf{C}_k \equiv \mathbf{N}\mathbf{G}_{k-5}\mathbf{G}_{k-6}[\bar{2}_{k-7}]\mathbf{G}_{k-7}[\bar{2}_{k-8}]\cdots\mathbf{G}_1[\bar{2}_0]\mathbf{G}_0$$

so that

$$\begin{aligned} \mathbf{C}_k &\in \mathcal{G}_0\{\bar{n}_{k-4}\bar{2}_{k-5}\cdots\bar{2}_0\} \\ &\equiv \Delta\text{map}:\kappa_0 \Rightarrow \kappa_0.(\Delta\tau:\kappa_0.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau) \rightarrow \\ &\quad (\Delta\tau:\kappa_0.\mathcal{I}((\bar{n}_{k-4}\bar{2}_{k-5}\cdots\bar{2}_0)\text{map } \tau) \rightarrow \mathcal{I}\tau) \\ &\triangleright \Delta\text{map}:\kappa_0 \Rightarrow \kappa_0.(\Delta\tau:\kappa_0.\mathcal{I}(\text{map } \tau) \rightarrow \mathcal{I}\tau) \rightarrow \\ &\quad (\Delta\tau:\kappa_0.\mathcal{I}(\text{map}^{f_{k-4}^{(n)}} \tau) \rightarrow \mathcal{I}\tau) \end{aligned}$$

■

The constant “-4” reflects the *kind overhead* of building pairs: the data structures in the construction, as well as the functionals acting on them, require a certain level of kind abstraction. We make no claim as to the optimality of this overhead; the goal of the analysis has rather been to show, for sufficiently large  $k$ , a bound on type inference for  $F_{k+1}$  that is at least exponentially harder than that for  $F_k$ . The cost of improving the constant would almost certainly be a pedagogically unnecessary complication of the proof.

## 6 Discussion; Open problems

We have provided the first lower bounds on type inference for the Girard/Reynolds system  $F_2$  and the extensions  $F_3, F_4, \dots, F_\omega$ . The lower bounds involve generic simulation of Turing Machines, where computation is simulated at the expression and type level simultaneously. Non-accepting computations are mapped to non-normalizing reduction sequences, and hence non-typable terms. The accepting computations are mapped to typable terms, where higher-order types encode the reduction sequences, and first-order types encode the entire computation as a circuit, based on a unification simulation of Boolean logic. Our lower bounds employ combinatorial techniques which we hope will be useful in the ultimate resolution of the  $F_2$  type inference problem, particularly the idea of composing polymorphic functions with different domains and ranges.

Even if our bounds are weak (if the  $F_2$  problem is undecidable, they certainly are!), the analysis puts forward a certain *program*; it remains to be seen how far that program can be pushed. While the higher-order systems are of genuine interest, it is  $F_2$  which occupies center stage: in particular, we would like to know if the techniques of the higher-order lower bounds can be “lowered” to  $F_2$ , somehow using the  $F_2$  *ranks* to simulate the expressiveness we have obtained from the *kinds* in  $F_3, F_4, \dots, F_\omega$ . The computational power of the kinds includes not merely higher-order quantification, but more importantly  $\beta$ -reduction at the type level.

Generic simulation is a natural setting for lower bounds, particularly when the complexity classes are superexponential, and there are few difficult combinatorial problems on which to base reductions. It seems equally natural that the *type information* added to an (untyped) term is of a length proportional to the time complexity of the TM being simulated. Furthermore, the program of generic simulation generalizes nicely, as expressed in the slogan, “how fast can the

crank (of the transition function) be turned?": better lower bounds can be proven by analyzing different "cranks." We observe in particular that the typing outlined in Section 5 was discovered by studying the reduction sequence of the *untyped* term  $C$  to normal form, and constructing the type as an *encoding* of that sequence. This analysis suggests an examination of  $F_2$  types, particularly in the light of the strong normalization theorem, as *encodings of reduction sequences*. Of course, these encodings are in general ambiguous since, for example, different Church numerals are not interconvertible under  $\beta$ - and  $\eta$ -reduction, and as such they cause different reductions to take place when used as iterators, yet they have the same type. Observe, however, that the programming style used to derive our lower bounds avoids exactly this kind of ambiguity: this is the essence of the duality of terms and types.

The nonelementary lower bound for  $F_\omega$  type inference should immediately call to mind a well-known theorem of Statman: the theorem states that if we have two  $\lambda$ -terms typable in the *first order* typed lambda calculus, deciding whether the terms have the same normal form requires nonelementary time [Sta79, Mai92b]. The proof of Statman's theorem is a reduction from deciding the truth of expressions in higher-order logic, where quantification is allowed not only over Boolean values, but over higher-order functions over Booleans [Mey74]. Every formula in higher-order logic is transformed, using the reduction, into a  $\lambda$ -term that  $\beta$ -reduces to the standard term  $\lambda t:\sigma.\lambda f:\sigma.t$  coding "true" if and only if the formula is true, and otherwise to the term  $\lambda t:\sigma.\lambda f:\sigma.f$  coding "false." We wish to emphasize both the abstract structural similarities between these results and the lower bounds described in this paper, as well as the necessary and profound structural differences at the level of detailed coding.

Introducing higher-order quantification and abstraction mechanisms in a calculus allows greater expressiveness and succinctness, and as a consequence, decision problems relating to expressions in the calculus invariably require greater computational resources. For example, deciding whether a propositional formula is true under a particular substitution of **true** and **false** for the variables is complete for polynomial time; this is the well-known *circuit value* problem [Lad75]. When we existentially quantify over the propositional variables, asking instead whether there exists a substitution for which the formula is true, we get the *satisfiability* problem, complete for nondeterministic polynomial time [Coo71, GJ79]. By alternating existential and universal quantifiers, we derive the polynomial time hierarchy, and in the limit, the problem of *quantified boolean formulas*, complete for polynomial space [SM73, GJ79]. Finally, if we allow quantification over functions of Booleans, functions of functions of Booleans, etc., we get a problem complete for nonelementary time [Mey74, Sta79].

The theorems described in this paper follow much the same pattern. First-order unification is complete for polynomial time [DKM84], corresponding to the complexity of first-order type inference. The progressively stronger lower bounds in this paper are derived by similarly allowing greater and greater functional abstraction on types. A further similarity between the Statman theorem and the  $F_\omega$ -bound is the particular use of the Church numeral for 2 as an iteration mechanism.

However, it is the problem of type inference, and not type equivalence, that is addressed in this paper. The structural similarity we have outlined above is between higher-order logic and the *type language* of  $F_\omega$ , yet the problem of type inference is not really about the type language, but rather a decision problem about untyped  $\lambda$ -terms. As a consequence, while in the problems of Meyer and Statman, where the logic (equivalently,  $\lambda$ -terms) can be manipulated *directly*, there is a certain inescapable *indirection* in our construction, where the types can only be "manipulated" by terms

at the value level. To render this manipulation unambiguous, we have used the idea of making reductions at the value level correspond exactly to constructs at the type level. There is of course no such correspondence when the term at the value level does not strongly normalize, a situation that has no proper analogue. To summarize, while there are certainly high-level similarities—and indeed, this is what gives a certain classical flavor to our analysis from the perspective of complexity theory—the details are quite dissimilar, and for important structural reasons.

Finally, we should observe as well the pitfalls of the methods introduced and used in this paper, or at least the hurdles which wait to be surmounted. The “cranks” described are all strongly normalizing in a manner such that, while one might aspire to better lower bounds (say, at the level of non-primitive recursion) we will never get an undecidability result. As long as we pursue bounds for  $F_2$  based on expressiveness of the type language, we are constrained by the strong normalization theorem, and the representation theorem (that the representable integer functions are those provably total in second order Peano Arithmetic) [Gir72, GLT89]. We have some idea how to get around the first hurdle, but are a bit puzzled by the second. Does it seem possible that the representation theorem would allow reduction sequences of functionally unbounded length on typable terms?

This latter suggestion deserves further development; we sketch here how such an undecidability proof might look. It is clear that any theorem of the form “ $\lambda$ -term  $E$  is typable iff TM  $M$  halts” cannot be proved if  $E$  contains the fixpoint combinator  $\mathbf{Y} \equiv \lambda f.(\lambda x.f(xx))(\lambda x.f(xx))$ , since  $\mathbf{Y}$  is not strongly normalizing, and hence not typable in any of the type systems we have considered. However, consider the following variant of  $\mathbf{Y}$ :

$$\overline{\mathbf{Y}} \equiv \lambda f.(\lambda x.f(\lambda y.yxx))(\lambda x.f(\lambda y.yxx)).$$

Notice that  $\overline{\mathbf{Y}}$  is, in contrast, strongly normalizing: writing  $\overline{\mathbf{Y}} \equiv \lambda f.H_f H_f$ , its normal form is  $\lambda f.f(\lambda y.y H_f H_f)$ . Could we use such a combinator to code an unbounded computation?

Consider a  $\lambda$ -term  $F$  of the form

$$F \equiv \lambda choose.\lambda ID.choose ((halt? ID) (\lambda p.\lambda q.I) I) (\delta ID),$$

where we code a halting predicate  $halt?$  on IDs, using conventional techniques. Let  $ID_0$  be an initial ID; then in the case that  $halt? ID_0 \triangleright true \equiv \lambda x.\lambda y.x$ , so that a halting configuration has been reached, we have

$$\begin{aligned} \overline{\mathbf{Y}} F ID_0 &\triangleright F (\lambda y.y H_F H_F) ID_0 \\ &\triangleright (\lambda y.y H_F H_F) ((halt? ID_0) (\lambda p.\lambda q.I) I) (\delta ID_0) \\ &\triangleright (\lambda y.y H_F H_F) (\lambda p.\lambda q.I) (\delta ID_0) \\ &\triangleright (\lambda p.\lambda q.I) H_F H_F (\delta ID_0) \\ &\triangleright \delta ID_0 \\ &\triangleright ID_0. \end{aligned}$$

On the other hand, if  $halt? ID_0 \triangleright false \equiv \lambda x.\lambda y.y$ , we derive

$$\begin{aligned}
\overline{Y} F ID_0 &\triangleright F (\lambda y.y H_F H_F) ID_0 \\
&\triangleright (\lambda y.y H_F H_F) ((halt? ID_0) (\lambda p.\lambda q.I) I) (\delta ID_0) \\
&\triangleright (\lambda y.y H_F H_F) I (\delta ID_0) \\
&\triangleright H_F H_F (\delta ID_0) \\
&\triangleright F (\lambda y.y H_F H_F) (\delta ID_0),
\end{aligned}$$

where the latter term is also a reduct of  $\overline{Y} F (\delta ID_0)$ . Instead of an uncontrolled unwinding  $F(F(F(\dots)))$  via the  $\mathbf{Y}$ -combinator, we get a controlled unwinding guided at every step by the state of the TM computation.

This construction shows that the set of strongly normalizing terms is not recursive, by constructing a term that strongly normalizes iff a particular TM computation halts.<sup>14</sup> In the case of a divergent TM computation, the  $\lambda$ -term is clearly not normalizing, and hence not typable. In the case of a convergent computation, can the  $\lambda$ -term be typed? We mentioned above our puzzlement with the representation theorem, yet the solution to the puzzle may be that unbounded computation is indeed allowed; however, the type of the (strongly normalizing) term explicitly codes the reduction sequence.

We conclude with a final *caveat lector*. The lower bound we have proven for  $F_\omega$  is unlikely to be improved further by naively trying a better “crank,” unless the foundation of the simulation is changed substantially. The explanation of this limitation is that the *type* language of  $F_\omega$  is fundamentally, as we have described earlier, the first-order typed  $\lambda$ -calculus with a single type constant (\*). The “duality” approach forces reductions at the expression level to match those at the type level, and a result of Schwichtenberg [Sch82] indicates that our construction is using the type language at its maximum capacity. Encouraged and excited as we are to have made progress on these open questions in programming language theory, the hard work may have only just begun.

**Acknowledgements.** The results of Section 3 were reported earlier in [Hen90]. For their encouragement, suggestions and criticisms, we thank Paris Kanellakis, Georg Kreisel, Daniel Leivant, Angus Macintyre, Albert Meyer, Jon Riecke, and Rick Statman. The second author wishes to acknowledge the generosity of the Computer Science Department at UC Santa Barbara, the Music Academy of the West, and the Cate School of Carpenteria, for their hospitality during his visit to Santa Barbara in the summer of 1990. He would also like to thank the Cambridge Research Laboratory of Digital Equipment Corporation, where final work on the paper was completed.

---

<sup>14</sup>This is of course a simply corollary of the Scott-Curry undecidability theorem (see, for example, [HS65]).
