AIM: To evaluate the palliative therapeutic effects of transjugular intrahepatic portosystemic shunt (TIPS) in portal vein tumor thrombosis (PVTT) complicated by portal hypertension.

METHODS: We performed TIPS for 14 patients with PVTT due to hepatocellular carcinoma (HCC). Of the 14 patients, 8 patients had complete occlusion of the main portal vein, 6 patients had incomplete thrombosis, and 5 patients had portal vein cavernous transformation. Clinical characteristics and average survival time of 14 patients were analysed. Portal vein pressure, ascites, diarrhea, and variceal bleeding and circumference of abdomen were assessed before and after TIPS.

RESULTS: TIPS was successful in 10 cases, and the successful rate was about 71%. The mean portal vein pressure was reduced from 37.2 mmHg to 18.2 mmHg. After TIPS, the ascites decreased, hemorrhage stopped and the clinical symptoms disappeared in the 10 cases. The average survival time was 132.3 d. The procedure failed in 4 cases because of cavernous transformation in portal vein and severe cirrhosis.

CONCLUSION: TIPS is an effective palliative treatment to control hemorrhage and ascites due to HCC complicated by PVTT.

MATERIALS AND METHODS

Clinical data
There were 14 patients with end-stage HCC in our hospital from December 1998 to May 2001, 13 men and one woman. The patients aged from 28 to 75 years, and the average age was 56.3 years. Three patients did not receive any treatment before TIPS and the others were treated with transarterial chemoembolization (TACE) and other procedures. One patient survived for 6 years after 8 times of TACE, and 2 patients emerged ascites and hemorrhage after they were treated by radiofrequency ablation. Of the 14 patients, there were three patients with intractable ascites, one patient with simple hemorrhage and 10 patients with hemorrhage and ascites (Tables 1, 2). Their hepatic function was poor and assigned to Child-Pugh class C. The diagnosis of PVTT was based on contrast-enhanced CT and color Doppler sonography while the cavernous transformation in the portal vein was detected by color Doppler sonography, contrast-enhanced CT and angiography.

TIPS procedure
TIPS was performed by using the RTPS 100 (Cook, America) portal venous puncture set. After administration of local anesthetic (20 g/L lidocaine hydrochloride) the Colapinto needle (Cook, America) was advanced into the right hepatic vein, and then the right portal vein was punctured. A wire guide (hydrophilic coating wire guide, Terumo) was introduced through the needle. Because of stenosis, occlusion and cavernous transformation of portal vein trunk and its right and left branches, puncture was difficult. So small branches were also available. With a guiding wire the catheter was advanced into the portal vein trunk. After measurement of the portal venous pressure, the needle track was dilated with a balloon (10 mm-diameter, 40 mm-length). Then an expandable stent (8-10 mm-diameter, 6-8 cm-length) was placed. The number of stents was based on the length of the shunt tract to ensure the stents covering all along stenosis segments arising from tumor emboli. The portal venous pressure was also measured after shunt was established.

RESULTS
The portosystemic shunt was successful in 10 of 14 patients. Shunt tract was achieved with a single stent in four patients, two stents in four patients, and four stents in two patients. The mean portal pressure was 37.2 mmHg and 18.2 mmHg before...
and after TIPS. The mean abdomen circumference was 86.3 cm and 77.65 cm before and after the procedure (Table 1). TIPS could be performed for four patients with incomplete occlusion of portal vein trunk as standard TIPS (Figure 1), while it could be performed for six patients with complete occlusion of portal vein trunk by introducing hydrophilic coating wire guide through the potential vascular lumen to superior mesenteric vein (Figure 2). The 4 patients with cavernous transformation in portal vein and severe cirrhosis failed to TIPS procedure, no portal vein trunk and branches but vascular plexus sign was displayed on angiogram. They had no improvement in clinical symptoms and their mean survival time was 34 days, shorter than the successful ones. The needles were punctured out of liver and into the peritoneum cavity in two patients, but they had no severe complications during and after the procedure. The needle tract was passed through the tumor in one patient, but no metastasis was found in 3 mo of follow-up. In all patients the mean content of serum bilirubin and aminotransferase increased transiently after TIPS procedure, and improved after one week of treatment.

Figure 1 TIPS procedure in patient with incomplete occlusion of portal vein trunk. A: Main portal vein dilation with eccentric tumor thrombi shown on enhanced Ctgram. B: Superior mesenteric vein dilation with eccentric filling defect and main portal vein occlusion shown on superior mesenteric vein angiogram. C: Open shunt shown on superior mesenteric vein angiogram after stent implantation. D: Recurrence of symptoms of ascites and diarrhea 30 d after TIPS and shunt stenosis as well as segmental filling defects shown on follow-up angiogram.
DISCUSSION

The incidence of PVTT in end-staged HCC was very high, about 20-30% in small hepatoma (2-3 cm in diameter) and 50-75% in those above 5 cm in diameter, and 86% of HCC patients with variceal bleeding had PVTT\(^\text{[18]}\). The tumor emboli resulting in portal hypertension and high resistance made the patients tend to have variceal bleeding and ascites. Tumor thrombosis in main portal vein was more prone to variceal bleeding and more difficult to be treated than that in branches and hepatic vein. Therefore some conservative measures were taken to relieve the patients’ ailments, such as endoscopic sclerotherapy and ligation. But these measures were less effective. Because of low efficacy and huge cost, many patients abandoned treatment.

Current status and application of TIPS in PVTT

TIPS procedure is an effective and safe treatment for patients with variceal hemorrhage and intractable ascites, but its use is limited due to its complications of encephalopathy and poor long-term efficacy\(^\text{[19-25]}\). It was reported that the rate of stenosis of shunt was 33-66% within 1 year and that of encephalopathy was 10-30%\(^\text{[1-2,19,22]}\). In recent years some scholars applied TIPS to portal hypertension secondary to portal thrombosis to ensure the patients to have time for further treatments including liver transplantation\(^\text{[26-29]}\). But the thrombus must be newly happened because old emboli possibly led to cavernous transformation and made the TIPS and liver transplantation difficult. Some authorities applied TIPS to HCC patients with esophagogastric variceal bleeding, but they thought that patients must be with hepatic function class A or B (Child-Pugh classification), under-controlled or small nodular type hepatoma and without PVTT\(^\text{[18,30-34]}\).

Key skill points in TIPS procedure for PVTT

Of the 14 cases, 10 cases were technically successful and the ratio of success was consistent with that reported\(^\text{[1-2]}\). It was very difficult to puncture the right main portal branch directly because of portal occlusion, stenosis and cavernous transformation. Even a small branch of portal vein was punctured with good blood regurgitation, and hydrophilic coating wire guide could be introduced into the superior mesenteric vein or splenic vein through the loose thrombus (Figure 2). The stent should cover all the thrombus to prevent tumor from growing into the shunt. The slower the blood flow passing the stent, the more easily the shunt was thrombosed. Esophagogastric vein should be embolized after TIPS procedure because low blood flow tended to form thrombosis in the shunt\(^\text{[18,25]}\). The embolism of esophagogastric vein could also prevent variceal bleeding, keep high flow and reduce thrombosis in the stent. But esophagogastric vein was not displayed very well because of PVTT in most cases.

Experiences and clinical effect

TIPS procedure is very effective for diarrhoea secondary to PVTT. A male patient with PVTT had mechanical diarrhoea 12-15 times a day and it lasted for a month with no abnormality in stool examination. Following the decrease of portal pressure after TIPS, ascites and diarrhoea decreased. The causes of diarrhoea were similar to those of ascites. Too high portal vein pressure could make fluid leak out of vessels not only into peritoneal cavity but also into intestinal tract as watery stool.

All patients who failed to TIPS procedure had cavernous transformation. Two patients with tumor thrombus in portal vein had no dilation in superior mesenteric vein and the pressure was not high as well (Figure 3). Considering that the effect was probably not very well in patients with little pressure gradient, we did not continue further procedure. In these portal hypertension patients there were areas with both a portal and a systemic venous drainage including esophageus, anal canal, retroperitoneum and umbilical region. Partial spleen artery embolization or gastric coronary vein embolization was not effective and variceal rebleeding was inevitable in the following months. In this study only one patient had a successful procedure in five patients with cavernous transformation, so it should be careful to carry out TIPS procedure in such cases.

Figure 2 Occlusive portal vein, dilated superior mesenteric vein, portal vein cavernous transformation, and esophagogastric varices shown on portal vein angiogram after introducing a catheter into superior mesenteric vein.

Figure 3 Main portal vein occlusion, hepatic arteric portal shunt and portal cavernous transformation in a 64-year-old patient with refractory ascites and hematemesis. A: Thin splenic and superior mesenteric vein shown on enhanced CT gram. B: Thin superior mesenteric vein and disordered drainage vein shown on angiogram.
monitoring condition change, patients in this study did not have encephalopathy of stage II and only 5 patients had transitory encephalopathy of stage I. Although patients died of dyscrasia or liver failure, their quality of life was improved.
