Received 9 March 2005/Returned for modification 22 April 2005/Accepted 4 May 2005

Paracoccidioidomycosis (PCM), caused by Paracoccidioides brasiliensis, is a chronic granulomatous systemic mycosis prevalent in rural areas of Latin America (16). PCM is routinely diagnosed by culture observation and microscopic detection of yeast cells in clinical specimens (10) and by serological tests, particularly with gp43, a reference P. brasiliensis antigen (17, 18).

Molecular methods (2, 6, 11, 19) allow the identification of many fungi without the need of culturing. They are rapid, highly specific and sensitive (3). The molecular identification of P. brasiliensis with primers of diverse origin has been reported (4, 5, 7, 9, 13, 14). Two specific DNA fragments (0.72 and 0.83 kb) common to and specific for all P. brasiliensis strains are generated when the arbitrary primer OPG18 (Operon Biotechnology) is used (5). We report specific primers designed on the 0.72-kb fragment, capable of identifying P. brasiliensis DNA from sputum and cerebrospinal fluid (CSF) of PCM patients.

P. brasiliensis DNA (strain Pb73; ATCC 32071) was prepared as described before (5). Other DNA samples were Histoplasma capsulatum (strains 7090, G222B, and G217B), Aspergillus terreus, Aspergillus fumigatus, Aspergillus nidulans, Blastomyces dermatitidis (strains 4.1 and 4.2), Candida albicans (strains B102A and 3), Candida krusei (strain W0701), Candida parapsilosis (strain 8992), Candida tropicalis (strain W0739), Candida guilliermondii (strain 6742), Candida pseudotropicalis (strain W0696), Candida dubliniensis, Cryptococcus neoformans (strain 90-2), Penicillium marneffei (strain 10742), Sporothrix schenckii (strain 5038), Trichophyton rubrum (strain A), Mycobacterium tuberculosis, Mycobacterium bovis, and Mycobacterium smegmatis.

Primers were designed on the 0.72-kb fragment generated by PCR with the arbitrary primer OPG18 (Operon Biotechnologies) (5). They were as follows: MG2(1)F, 5′-ATGCTAATTTATGTCATTCCGCGTCTG-3′; MG2(1)R, 5′-GTGCAGTGATCTGACGTTAGTACGTGATG-3′; MG2(2)F, 5′-TTATCCACAAGCCATATATTC-3′; and MG2(2)R, 5′-ATGCTAATTTATGTCATTCCGCGTCTG-3′.

PCRs were carried out in 25-μl reaction mixtures with 2.5 μl 10× PCR buffer (200 mM Tris-HCl, p 8.4, 500 mM KCl) containing 20 ng genomic DNA, 20 pmol of each primer, 0.75 μM MgCl2, 1.25 μM 1 mM dNTP, and 0.5 U Taq DNA polymerase (Life Technologies). Amplifications were performed in a thermocycler (MJ Research, Inc.) with an initial cycle of 94°C (5 min), 30 cycles of 94°C (30 s), 50°C (30 s), and 72°C (1 min), and a final extension for 5 min at 72°C. Negative controls (water instead of fungal DNA) were included in all reactions. Sensitivity of the PCR assay was tested with P. brasiliensis genomic DNA at concentrations from 5 ng to 1 pg.

For diagnostic purposes, seven sputa and one CSF sample from PCM patients (Table 1) and three sputum samples from subjects without PCM were tested, undiluted and in 1:5 and 1:10 dilutions. An initial PCR with 5 μl DNA and the primer pair MG2(1)F-MG2(1)R was carried out, followed by reamplification (2 μl) under the same conditions. Southern hybridization with the specific 0.72-kb probe (5) was carried out according to the methods in reference 15.

To evaluate the method, control spuata were spiked with P. brasiliensis yeast cells (0, 10, 102, and 105 cells/ml). Samples were treated according to the methods in reference 8, although modifications were needed. (i) The lysis buffer consisted of 0.1 M Tris-HCl, pH 7.5; 5% sodium dodecyl sulfate; 30 mM EDTA; and both chitinase (from Streptomyces griseus, 1 mg/ml; Sigma, St. Louis, MO) and β-glucanase (yeast lytic enzyme, 2 mg/ml; ICN Biomedicals Inc., Aurora, OH) as lytic enzymes to soften the P. brasiliensis cell wall. It was added 1:1 (vol/vol) for 2 h at 37°C and a further 15 min at 100°C. (ii) Centrifugation conditions were modified to 12,000 rpm for 5 min after the potassium acetate step, 5,000 rpm at 4°C for 10 min after the phenol-chloroform extract, and 8,000 rpm at 4°C for 5 min following overnight incubation at −20°C.

Patients (Table 1) were farmers from rural areas nearby the Valencia Lake, in the north-central region of Venezuela (patients 1 through 7), or Lara State, the central-western region of the country (patient 8). Samples were treated in the same fashion as spiked samples. The project was submitted to and approved by the Bioethics Commission of the Venezuelan Institute for Scientific Research.

| 8a      | M (38)          | Chronic, multifocal PCM, with involvement of the central nervous system | + +                    | CSF biochemistry revealed a discreet elevation in proteins. Direct microscopic examination, culture, and serology (DID) for P. brasiliensis were negative. CT scan with contrast showed the presence of multiple hypodense images with ring enhancement, surrounded by mild edema, localized mainly at posterior fossa and in lower numbers in basal ganglia and around periventricular.

DNA from all microorganisms listed above were used for PCR assays with primer pairs MG2(1)F-MG2(1)R and MG2(2)F-MG2(2)R. Figure 1 shows results obtained with P. brasiliensis, B. dermatitidis, H. capsulatum, C. albicans, C. dubilienis, A. nidulans, and A. fumigatus. All other fungal and mycobacterial DNAs and DNA from control samples were negative. Specific P. brasiliensis bands of 285 bp [MG2(1)F-MG2(1)R] and 288 bp [MG2(2)F-MG2(2)R] were generated. Southern hybridization (not shown) was positive for the P. brasiliensis amplicon only, confirming the specificities of the designed primers. They had a sensitivity limit of 10 pg (Fig. 2). The limit for spiked sputum samples was 10 cells/ml. Thereafter, only primer pair MG2(1)F-MG2(1)R was used.

Experiments with serum and blood samples (not shown) were unsuccessful. With the exception of that of patient 2, samples listed in Table 1 generated a well-defined band (Fig. 3) visible even at a 1:10 dilution (not shown). Two sputum samples (those of patients 6 and 7) corresponded to previously treated PCM patients who returned to the hospital for presumptive PCM relapse. In both cases, molecular tests were done before clinical and laboratorial results were available. Sputum from patient 6 was positive for P. brasiliensis, while that from patient 7 was not. Clinical and mycological confirmations of both molecular diagnoses were reached at a later date.

So far, P. brasiliensis DNA sequences of potential diagnostic use include some derived from the rat β-actin gene (7), the 5.8S rRNA gene and its flanking internal transcribed spacer regions (9, 11, 13), or the gp43 gene (4, 8). The primers reported here produced positive identification bands in those patients with a confirmed diagnosis of chronic PCM, reflecting...
Treatment with amphotericin B diminished mucosal lesions suggestive of an involvement of the central nervous system (CNS). and developed neurological symptoms of impairment, suggests correctly predicted by the molecular test.

Interestingly, in two cases of suspected relapses (patients 6 and 7), the frequent pulmonary involvement in such cases (12). Interestingly, in two cases of suspected relapses (patients 6 and 7), our molecular test produced results that preceded, by one or more weeks, information obtained by clinical, serological, or our molecular test produced results that preceded, by one or more weeks, information obtained by clinical, serological, or mycological tests. One of these patients (patient 6) turned out to have a PCM relapse, while the other one (patient 7) did not, as correctly predicted by the molecular test.

As for patient 8, he suffered from chronic multifocal PCM, though antibody detection and microscopic observation were negative for the presence of the fungus in this sample, as usually reported for CNS PCM (1). A positive molecular test could avoid a stereotaxic biopsy of the brain for diagnosis and could be useful to follow the treatment of patients with paracoccidoidal CNS involvement.

We thank Bruno Maresca (International Institute of Genetics and Biophysics, CNR, Naples, Italy) for kindly providing the P. brasiliensis 789-bp fragment, George Kobayashi (Washington University, Division of Infectious Diseases, St. Louis, MO) for providing DNA samples of fungi other than P. brasiliensis, Mireya Mendoza for mycelial preparation of P. brasiliensis and Howard Takiff (IVIC, Caracas, Venezuela) for mycobacterial DNA. We thank Carmen Elena Kannee and María José De Armas (Hospital Vargas, Caracas, Venezuela) for the kind gift of a CSF sample from patient 8.

This work was supported by grant no. 2000-6, Instituto Venezolano de Investigaciones Científicas (IVIC). F.H.-B. was the recipient of a United Nations University Fellowship Training at Instituto Venezolano de Investigaciones Científicas (August-December, 2002).
