E-mail: bratcliffe1@unl.edu

Abstract

The 541 species of Scarabaeoidea known to occur in Panama are listed. Synonyms are included when present. Names placed in new synonymy are *Pelidnota hirsutiphallica* Ratcliffe and Jameson (=*P. pubes* Ohaus) and *Bolax vittatus* Casey (= *B. magnus* Bates). All taxa are accompanied by an abbreviated reference to the original literature citation wherein they were described. A list of provinces in Panama in which each species is known to occur is also provided.

Key words: Coleoptera, Scarabaeoidea, Panama, checklist

Introduction

The Scarabaeoidea is a large, diverse, cosmopolitan group of beetles. It has about 35,000 species known and almost 200 new species are being described each year. Scarabaeoids have diversified into most habitats, and they are fungivores, herbivores, necrophages, coprophages, saprophages, and carnivores. Even though they are prominent members of the entomofauna, they are still poorly known taxonomically. The first attempt at an identification manual for the Central American Scarabaeoidea was written by Bates (1886-1890) in the *Biologia Centrali-Americanana* series. Since that time, nothing of a comprehensive nature has ever been written. The selected insect groups treated in Quintero and Aiello's (1992) *Insects of Panama and Mesoamerica* are only the tip of a very large iceberg, and the volume covered only the Passalidae out of all the scarabaeoids.

This is the first checklist devoted exclusively to the all the scarabaeoid beetles of Panama. It was compiled (with specimen verification wherever possible rather than simply taken at face value from catalogs) from traditional sources such as the *Coleopterorum Catalogus*, Blackwelder's (1944) checklist of the Coleoptera of Mexico, Central America, the West Indies, and South America, and Blackwelder and Arnett's (1974) checklist of the

beetles of Canada, the United States, Mexico, Central America, and the West Indies. In addition, all the recent papers and monographs covering certain specific taxa were consulted up to April 2002 (for example, Howden 1964 for Geotrupidae; Howden 1968 for Trichiinae; Howden and Young 1981 for Scarabaeinae; Howden and Gill 2000 for Ceratocanthinae; Hardy 1975 for *Pelidnota*; Morón 1990 and Hawks 2001 for *Chrysina* (=*Plusiotis*); Jameson 1998 for *Rutela*; Soula 1998 for Anticheirina; Ratcliffe in press for Dynastinae). Lastly, records from my collecting in Panama over the last 25 years are included along with those of colleagues who have also conducted extensive research and collecting there.

This list has shortcomings, however, because some groups (principally Passalidae, Ceratocanthidae, Aphodiinae, Melolonthinae, and *Anomala*) have not been comprehensively reviewed. Under these circumstances, new species await description while the names of some other species will undoubtedly be placed in synonymy. In Passalidae, for example, Reyes-Castillo and Castillo (1992) reported 25 species in Panama, but there may be as many as 55 species (A. Gillogly, personal communication 2000). Of those 30 additional species, about half are range extensions while the other half represent new species. My studies of the Dynastinae of Panama have also revealed a number of new species, some of which are now awaiting publication. In spite of the efforts of a few scientists, Panama has not yet been adequately surveyed for scarabaeoids. While scarab beetles remain a popular group to collect and study, there are still not enough systematists studying scarabs to resolve all the problems of taxonomy and classification . . . let alone to address the questions dealing with phylogenetic relationships, biogeography, and the basic biology of most of the species.

Panama is a relatively small country with a great amount of physiographic diversity that contributes directly to the richness of its biota. Like most Latin American countries, it is also undergoing increasingly intense land development where pristine areas are succumbing to "development." Contrast our lack of surveys and knowledge of the biota that exists in Panama with the rapidly disappearing tropical forests there, and it becomes clear that additional research is needed . . . and quickly if we are not to lose forever those species now in peril of having their habitats eliminated.

The National Research Council's Committee on Research Priorities in Tropical Biology recommended that emphasis on collecting be given to tropical areas because of their great biological diversity, high levels of endemism, and the rate at which tropical forests are being converted to other purposes (National Research Council 1980). It seems that resolutions by professional biological societies (Entomological Society of America, Coleopterists Society, Association of Systematics Collections, the 1992 "Earth Summit" held in Rio, Association of Tropical Biology, etc.) are made almost every year that support the efforts of national and international organizations in funding comprehensive biological surveys and the production of electronic databases, identification manuals, and monographs. Collection of new material and inventories of existing collections are needed in

order to explore and catalog biotic diversity and to facilitate further research. These are very different, but complimentary, components of biotic surveys. Insects, by virtue of their diversity and abundance, are critical to the success of maintaining any natural habitat. Too often, however, they are not considered in the management scheme of any threatened area. "Insects are major connectors between different species in their habitat, including species that have long been in the eye of the conservation community. By consuming large quantities of plants and plant parts on the one hand, and by being consumed in enormous amounts by vertebrates on the other hand, insects in great part determine the structural relationship between larger organisms. Those of you who wish to see vertebrates in tomorrow's national parks need to give serious consideration to the place of insects in the food and competition webs leading to those vertebrates" (Janzen 1987).

Approximately 20% of all species on Earth could be lost in the next few decades. More alarming than the mammal and bird losses, however, will be the extinction of large numbers of insects, plants, and fish . . many of them never even described or studied. At least half of these losses will result from tropical deforestation (Anonymous 1974, 1981; National Science Board 1989; Wilson 1992). The efficient and sane use of natural resources depends on accurate and detailed ecological knowledge. The major deterrent to these ecological studies, however, is the severe lack of taxonomic data that is the fundamental building block for all subsequent studies. In order to arrive at a sound view of ecology in tropical forests, we must first identify and catalog the fauna. This is an urgent task now requiring quick action (Alberch 1993). The growing recognition of the importance to humankind of tropical forests and the mounting concern for their future is now well known. The pace of basic research in the tropics must be accelerated, and failure to do so will eventually limit our capability to contribute solutions to impending scientific and human problems.

In Panama, the Scarabaeoidea is represented by 8 families. The largest family, Scarabaeidae, has 8 subfamilies with 122 genera and about 483 species represented in Panama. Among the larger subfamilies of Scarabaeidae, there are 36 species of Aphodiinae, 133 species of Scarabaeinae, a surprisingly low 50 species of Melolonthinae, 116 species of Rutelinae, 126 species of Dynastinae, and 24 species of Cetoniinae. In Panama there are now 152 genera and 541 species of Scarabaeoidea. This number *will* increase in the future.

After each species in the checklist, the provinces (Fig. 1) are listed in which it is known to occur. Many species lack an indication of province or have only a partial listing of provinces because there is either (1) only a country record, (b) there is no recent literature listing localities, or (c) the locality data is known by me to exist only in collections that have not yet been studied. It was not possible to survey all the collections containing scarabs from Panama to gather distributional data; that would be a huge task since most collections are not yet electronically databased. The designation of "CANAL ZONE" is used, even though it is now part of Panama province, because all of the material cited from

this area used that designation when collected (and are so labeled) and because it does more precisely delimit *where* in the otherwise large province of Panama the material was collected. The designation of “Canal Zone” is, today, a historical artifact, and its use is meant only to better place a species geographically.

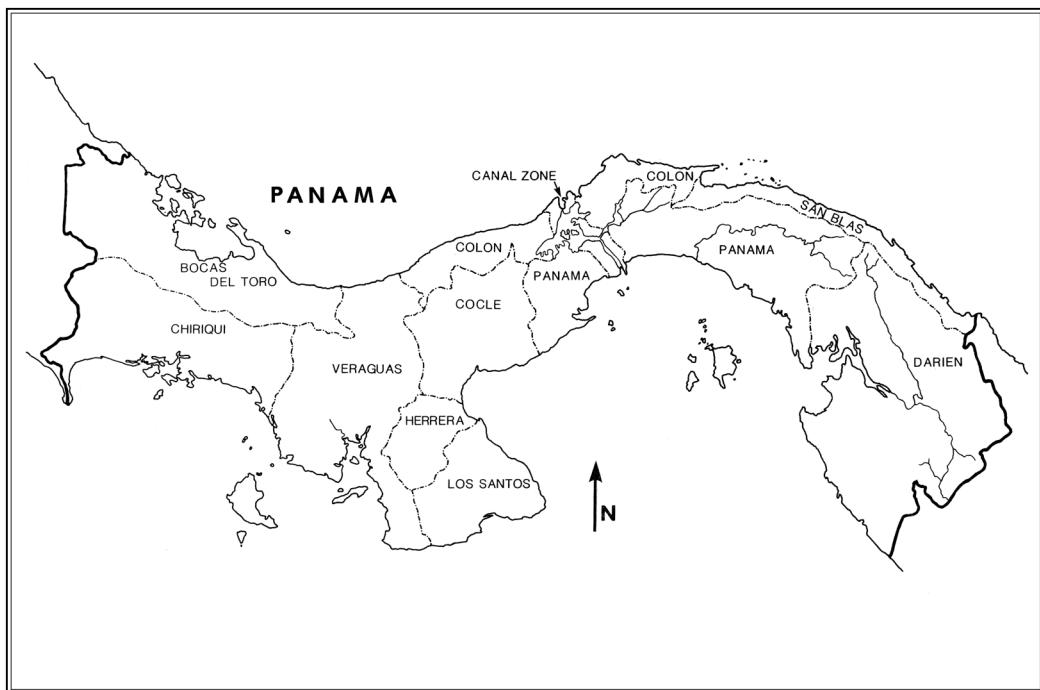

FIGURE 1. Map of Panama showing provinces.

Synonyms (in italics) for genera and species are provided for the taxon and are not limited to those described from Panama. Passalids are a notable exception (see remarks there) because the status of many taxa is changing rapidly. For certain large, cosmopolitan genera (*e.g.*, *Aphodius*, *Onthophagus*, *Anomala*), only the New World synonyms are provided; to do otherwise would create a very long list of names proposed for European and/or Asian taxa. A complete listing of non-New World generic synonyms is not the purpose of this work. Subspecies are provided, again for the taxon, and not limited to those occurring just in Panama. An appendix is provided wherein are listed the names of journals and books (many older and obscure) that may help the reader find literature. These were not completely spelled-out in the main body of the checklist in order to save space.

The primary audience for this checklist consists of systematists studying scarabaeoids, collections managers responsible for organizing collections, resource managers in parks and reserves in Panama, biogeographers needing lists of taxa for their analyses, a few applied entomologists needing information on occurrence or nomenclature, and Latin American students and teachers wanting to know more about their biota.

PASSALIDAE

Synonymies are not provided for passalids because the taxonomy is currently in a state of extreme flux, especially given that the fauna in Panama is probably twice as large as reported in this list. Many generic and species synonyms listed in catalogs are being removed from synonymy or transferred to other genera.

Acknowledgements

I am grateful to my students, Andrew Smith, Aura Paucar, and Federico Ocampo (University of Nebraska State Museum) who all generously provided additional records and information. Mary Liz Jameson and especially Andrew Smith (University of Nebraska) and Henry Howden (Canadian Museum of Nature) are gratefully acknowledged for reviewing the manuscript and making many additions and corrections. I thank Chris Marshall (Cornell University) and Alan Gillogly (Texas A & M University) for additional information on the occurrence of passalids in Panama. Over the many years that I have collected in Panama I have enjoyed the logistical support of Dodge Engleman, Henry Stockwell, and Ratibor Hartmann, all of whom shared with me their knowledge and deep appreciation of the biota of Panama. This paper was supported, in part, by an NSF/BS&I grant (DEB-9200760) to B. C. Ratcliffe and an NSF/PEET grant (DEB-9712447) to B. C. Ratcliffe and M. L. Jameson.
