## Abstract

All robotic systems require some form of motion control in order to build interesting behaviors. This is even more essential for multi-agent, highly-dynamic environments, such as robotic soccer. We present the motion control system used by CMUnited-98, the small-size league champion at RoboCup '98. We present the details of our motion vcontrol algorithm, and describe how its features help to build interesting and robust behaviors. We will also briefly compare our system to other motion control techniques.

## 1 Introduction

For any robotic system motion control is essential to building robust and interesting behavior. This is even more important for multi-agent systems that need to build team behaviors on top of individual behaviors. An example of such a system is robotic soccer. Here, a team of robots must coordinate their actions to push the ball into their opponents' goal. This is complicated by not only the opponent agents trying to prevent this from occurring, but also by the highly dynamic environment. This highly dynamic environment makes many traditional motion planning algorithms impractical since the environment changes before the planner can even finish its path.

This paper examines the motion control algorithm used in CMUnited-98 [6]. This team competed in RoboCup '98 in Paris in the small-size robot league. The team won four of its five games and was the league champion for the second straight year. A great deal of the success of the team can be attributed to the motion control algorithms. It not only made direct contributions by providing smooth and robust motion, but it's features allowed us to build powerful individual and team behaviors. In section 2, we give a brief overview of the architecture of our team. It

will describe the percepts and actuators available to the motion controller. In section 3, we describe the details of the motion control algorithm. In section 4, we describe how the high-level attacking behaviors effectively made use of our algorithm. Finally, in section 5 we will discuss related work in this area.

## 2 Team Architecture

The CMUnited-98 small-size robot team is a complete, autonomous architecture composed of the physical robotic agents, a global vision processing camera overlooking the playing field, and several clients as the minds of the small-size robot players. Fig. 1 sketches the building blocks of the architecture. The motion controller resides in the individual client modules and bridges the gap between the output of the vision processing system and the robots' motors.

Figure 1: The CMUnited architecture with global perception and distributed reaction.

The vision system provides the input to the motion controller. Since it overlooks the entire field, it can provide a complete view of the world. Our image processing algorithm reliably detects and tracks the position and orientation of our five robots, the position of the five opponents, and the position of the ball. Additionally it uses a Kalman-

Bucy filter to provide a reasonably accurate prediction of the ball’s velocity, both speed and direction. This information is computed and passed to the client modules approximately every thirtieth of a second.

The output of the motion controller is a physical robot. The robots have two motors and use differential drive for movement. The client modules, specifically the motion controller, sends the desired wheel velocities to its physical robot using radio communication. The radio communication supports five robots each receiving over twenty commands every second. Additionally, there is no local feedback mechanism on the robots. All control is done using only visual feedback through the motion controller.

A summary of the issues the motion controller must address are given below.

- Ten moving robots ( $\leq 12\text{cm}$  diameters) on a small walled field ( $152.5\text{cm}$  by  $274\text{cm}$ ). Robots are moving at speeds close to  $1\text{m/sec}$ .
- Vision system providing 30 frames per second. Radio communication able to support approximately 20 commands per second for each of the five robots.
- Must be able to push the ball towards a particular point, specifically towards a goal ( $50\text{cm}$  wide). It must also be able to intercept a moving ball and avoid fast moving obstacles.

### 3 Motion Control Algorithm

The goal of our motion control algorithm is to be as fast as possible while remaining accurate and reliable. This is challenging due to the lack of feedback from the motors, forcing all control to be done using only visual feedback. Our motion control algorithm is robust. It addresses stationary and moving targets with integrated obstacle avoidance. The algorithm makes effective use of the prediction of the ball’s trajectory provided by the Kalman-Bucy filter.

We achieve this motion control functionality by a reactive control mechanism that directs a differential drive robot to a target configuration. Though based on the CMUnited-97’s motion control [7, 1], CMUnited-98 includes a number of major improvements. The target configuration for the motion planner has been extended. The target configuration includes: (i) the *Cartesian position*; and (ii) the *direction* that the robot is required to be facing when arriving at the target position. Obstacle avoidance is integrated into this controller. Also, the target configuration can be given as a function of time to allow for the

controller to reason about intercepting the trajectory of a moving target.

#### 3.1 Differential Drive Control for Position and Direction

CMUnited-98’s basic control rules were improved from those used in CMUnited-97. The rules are a set of reactive equations for deriving the left and right wheel velocities,  $v_l$  and  $v_r$ , in order to reach a target position,  $(x^*, y^*)$ :

$$\begin{aligned} \Delta &= \theta - \phi & (1) \\ (t, r) &= (\cos^2 \Delta \cdot \text{sgn}(\cos \Delta), \sin^2 \Delta \cdot \text{sgn}(\sin \Delta)) \\ v_l &= v(t - r) \\ v_r &= v(t + r), \end{aligned}$$

where  $\theta$  is the direction of the target point  $(x^*, y^*)$ ,  $\phi$  is the robot’s orientation, and  $v$  is the desired speed (see Fig. 2(a))<sup>1</sup>.

We extend these equations for target configurations of the form  $(x^*, y^*, \phi^*)$ , where the goal is for the robot to reach the specified target point  $(x^*, y^*)$  while facing the direction  $\phi^*$ . This is achieved with the following adjustment:

$$\theta' = \theta + \min\left(\alpha, \tan^{-1}\left(\frac{c}{d}\right)\right),$$

where  $\theta'$  is the new target direction,  $\alpha$  is the difference between our angle to the target point and  $\phi^*$ ,  $d$  is the distance to the target point, and  $c$  is a clearance parameter (see Fig. 2(a).) This will keep the robot a distance  $c$  from the target point while it is circling to line up with the target direction,  $\phi^*$ . This new target direction,  $\theta'$ , is now substituted into equation 1 to derive wheel velocities.

In addition to our motion controller computing the desired wheel velocities, it also returns an estimate of the time to reach the target configuration,  $\hat{T}(x^*, y^*, \phi^*)$ . This estimate is a crucial component in our robot’s strategy. It is used both in high-level decision making, and for low-level ball interception, which is described later in this section. For CMUnited-98,  $\hat{T}(x^*, y^*, \phi^*)$  is computed using a hand-tuned linear function of  $d$ ,  $\alpha$ , and  $\Delta$ .

#### 3.2 Obstacle Avoidance

Obstacle avoidance was also integrated into the motion control. This is done by adjusting the target direction of the robot based on any immediate obstacles in its path. This adjustment can be seen in Fig. 2(b).

<sup>1</sup>All angles are measured with respect to a fixed coordinate system.

Figure 2: (a) The adjustment of  $\theta$  to  $\theta'$  to reach a target configuration of the form  $(x^*, y^*, \phi^*)$ ; (b) The adjustment of  $\theta'$  to  $\theta''$  to avoid immediate obstacles.

If a target direction passes too close to an obstacle, the direction is adjusted to run tangent to a preset allowed clearance for obstacles. Since the motion control mechanism is running continuously, the obstacle analysis is constantly replanning obstacle-free paths. This continuous replanning allows for the robot to handle the highly dynamic environment and immediately take advantage of short lived opportunities.

### 3.3 Moving Targets

One of the real challenges in robotic soccer is to be able to control the robots to intercept a moving ball. This capability is essential for a high-level ball passing behavior. CMUnited-98's robots successfully intercept a moving ball and several of their goals in RoboCup-98 were scored using this capability.

This interception capability is achieved as an extension of the control algorithm to aim at a stationary target. Fig. 3(a) illustrates the control path to reach a stationary target with a specific direction, using the control mechanism described above. Our extension allows for the target configuration to be given as a function of time, where  $t = 0$  corresponds to the present,

$$f(t) = (x^*, y^*, \phi^*).$$

At some point in the future,  $t_0$ , we can compute the target configuration,  $f(t_0)$ . We can also use our control rules for a stationary point to find the wheel velocities and estimated time to reach this hypothetical target as if it were stationary. The time estimate to reach the target then informs us whether it is possible to reach it within the allotted time. Our goal is to find the nearest point in the future

where the target can be reached. Formally, we want to find,

$$t^* = \min\{t > 0 : \hat{T}(f(t)) \leq t\}.$$

After finding  $t^*$ , we can use our stationary control rules to reach  $f(t^*)$ . In addition we scale the robot speed so to cross the target point at exactly  $t^*$ .

Unfortunately,  $t^*$ , cannot be easily computed within a reasonable time-frame. We approximate this value,  $t^*$ , by discretizing time with a small time-step. We then find the smallest of these discretized time points that satisfies our estimate constraint. An example of this is shown in Fig. 3(b), where the goal is to hit the moving ball.

The target configuration as a function of time is computed using the ball's predicted trajectory. Our control algorithm for stationary points is then used to find a path and time estimate for each discretized point along this trajectory, and the appropriate target point is selected.

## 4 Using Motion Control

We have described how our motion controller computes the wheel velocities to reach a target configuration,  $(x^*, y^*, \phi^*)$ , which may even be a function of time,  $f(t)$ . It is the responsibility of individual and team behaviors to select the appropriate target configurations for each of the robots. The features of our motion controller often simplify this problem. We will examine how these features help build two attacking behaviors, shooting and passing. Also, we will show how it contributes to our team attacking behavior, which involves a decision theoretic action selection.

Figure 3: (a) Control for a stationary target. (b) Control for a moving target.

#### 4.1 Individual Behaviors: Shooting and Passing

We first developed individual behaviors for passing and shooting. For both behaviors the positional portion of the target position is the ball’s position, since the goal is to push the ball. Additionally, we can use the ball’s predicted trajectory to make the position a function of time, according to the trajectory.

The directional portion of the target configuration determines where the ball is pushed. The passing behavior specifies a direction that is a small amount in front of the designated receiver. For shooting, a more complex target direction is computed. Simply pushing the ball towards the center of the goal will do nothing to avoid pushing the ball into the goalie. Instead, we want to push the ball towards the largest unblocked portion of the opponent’s goal. This is done by selecting the largest unblocked angular section of the goal and aiming for the angle that bisects it. Figure 4 illustrates the selected target configuration to achieve passing and shooting.

#### 4.2 Team Behavior: Decision Theoretic Action Selection

Given the individual behaviors, we must select an active agent, the agent that will go to the ball, and an appropriate behavior, passing or shooting. This is done by a decision theoretic analysis that uses a single step look-ahead. With  $n$  agents there are  $n^2$  choices of actions involving shooting or a pass to another agent followed by that agent shooting. An estimated probability of success for each pass and shot is computed along with the time estimate to complete the action, which is provided by the motion controller. With these estimates, a value for each action is

computed,

$$\text{Value}_{\text{pass}} = \frac{\text{Pr}_{\text{pass}}\text{Pr}_{\text{shoot}}}{\hat{T}(f_{\text{pass}})} \quad \text{Value}_{\text{shoot}} = \frac{\text{Pr}_{\text{shoot}}}{\hat{T}(f_{\text{shoot}})}$$

The action with the largest value is selected, which determines both the active agent and its behavior. Table 1 illustrates an example of the values for the selection considering two attackers, 1 and 2.

It is important to note that this action selection is occurring on each iteration of control, approximately 30 times per second. The probabilities of success, estimates of time, and values of actions, are being continuously recomputed. This allows for quick changes of actions if shooting opportunities become available or collaboration with another agent appears more useful.

## 5 Related Work

An alternative to our purely reactive algorithm is to use a complex motion planning algorithm. A number of these algorithms are summarized by Latombe [3]. These techniques find complete obstacle free paths, but yet have difficulties in the robotic soccer domain. Since the environment is highly dynamic with the obstacles constantly moving, planned paths would need to be constantly reevaluated. These algorithms are too slow for the continuous real-time execution that is demanded in robot soccer.

Another approach to motion control [4] uses a reactive mechanism with fast hardware-supported feedback, via motor encoders and on-board sensors. This makes use of a slower decision loop to provide high-level commands, and a fast control loop to perform these commands. The control loop uses the motor encoders to perform accurate movements and on-board sensing for immediate obstacle avoidance and ball manipulation. This was successfully used by CURF (Cambridge University Robot Football) in RoboCup ’98. One drawback to this technique is that the

Figure 4: An example of possible aiming positions given the position of the ball and two opponents. The largest angle is chosen and  $\phi^*$  is the bisection of the angle.

Attacker	Action	Probability of Success		Time(s)	Value
		Pass	Shoot		
1	Shoot	–	60%	2.0	0.30
1*	Pass to 2	60%	90%	1.0	0.54
2	Shoot	–	80%	1.5	0.53
2	Pass to 1	50%	40%	0.8	0.25

Table 1: Action choices and computed values are based on the probability of success and estimate of time. The largest-valued action (marked with the \*) is selected.

fast control loop does not have access to the complete sensors (i.e. the global view of the field), and short lived opportunities, which may not be recognized by the local sensors, often cannot be exploited. ISpace [2], another team that competed in RoboCup '98, used a similar technique, but due to onboard vision could possibly overcome this drawback.

Additionally, there are also other reactive control systems for remotely controlled robots[5].

## 6 Conclusion

We've described the motion control algorithm used in CMUnited-98. The algorithm incorporates obstacle avoidance, and has an extended target configuration that includes orientation and can be given as a function of

time. In addition to the details of the algorithm, we also described how its features simplifies the building of individual and team behaviors. The system was integral part of the team's success.
